FOREWORD

The work reported here was performed under the direction of the Oak Ridge National Laboratory (ORNL) in support of the ORNL Piping Program for the U.S. Atomic Energy Commission prior to formation of the U.S. Department of Energy. The experimental work was done at Southwest Research Institute (SwRI), and the data were analyzed and tabulated at ORNL. The material presented in this report was collected and summarized at Mechanics Research Institute (MRI) under subcontract to ORNL. Publication of the report was funded by the David W. Taylor Naval Ship Research and Development Center (DTNSRDC), Annapolis, Maryland, under contract No. 61533-80-GO-00016. L. M. Kaldor, Code 2744, DTNSRDC, is the project engineer. S. E. Moore, Engineering Technology Division, ORNL, is the program manager.

ACKNOWLEDGMENTS

The study described in this report spanning the course of several years is a result of the combined efforts of many people. Without their uniformly high professionalism, the study could not have reached its logical conclusion and perhaps could not have been conducted at all. We offer our sincere gratitude to: L. E. Alsager and J. L. Mershon, both retired from the United States Atomic Energy Commission, who foresaw the need for and were instrumental in establishing and nurturing the effort as a funded program; to D. F. Landers, S. W. Taggart, E. C. Rodabaugh, and B. F. Langer (deceased), who drafted the original test proposal and established the cooperative Pressure Vessel Research Committee effort; W. L. Greenstreet, who initiated and directed the Oak Ridge National Laboratory participation; J. E. Smith and S. E. Bolt, who formulated the test specifications and directed the experiments; G. W. Deel, who supervised the testing and laboratory work; W. G. Dodge, R. C. Gwaltney, and J. W. Bryson, who developed the analytical methods and analyzed the data; F. S. G. Williams (Taylor Forge, Inc.); D. K. Greenwald (Ladish, Inc.), and H. H. George (Tube Turns Division of Chemetron Corporation), who selected the test specimens; J. R. McGuffey and J. N. Robinson (deceased), who inspected the models; and others, who performed the many tasks required for a successful test program.

We also gratefully acknowledge the assistance of the Engineering Technology Division Word Processing Center and Publications Office for final preparation.

EXPERIMENTAL STRESS ANALYSIS AND FATIGUE TESTS
OF FIVE 12-in. NPS ANSI STANDARD B16.9 TEES

S. E. Moore S. C. Grigory*
R. A. Weed†

ABSTRACT

Experimental stress analyses and low-cycle fatigue tests of five 12-in. ANSI Standard B16.9 forged tees are documented in this report. The tees, designated as Oak Ridge National Laboratory (ORNL) tees T-4, T-6, T-7, T-8, and T-15, were tested under subcontract at Southwest Research Institute, and the data were analyzed at ORNL.

Experimental stress analyses were conducted for 13 individual loadings on each tee, including internal pressure and 3 mutually perpendicular force and moment loads on the branch and on the run. Each test model was instrumented with ~220, 1/16-in. three-gage, 45° strain rosettes on the body of the tee, and ~10, 1/16-in. two-gage, strain rosettes on the pipe extensions. Dial indicators, mounted on a special nonflexible holding frame were used to measure deflections and rotations of the pipe extensions. Normalized maximum stress intensities for each loading condition on each tee are summarized in the text. Complete sets of strain-gage data, normalized stresses, and displacement measurements for each tee are given on microfiche in the appendixes.

Following completion of the strain-gage tests, each tee was tested to failure in a fully reversed displacement-controlled low-cycle fatigue test with an alternating transverse load applied to the branch pipe. The load was directed out of plane for T-4, T-6, T-8, and T-15; and in plane for T-7. A constant internal pressure equal to the nominal design pressure was maintained during the fatigue tests. Failure data from the fatigue tests are summarized in the text.

Keywords: experimental stress analysis, fatigue, nuclear piping, piping design, ANSI B16.9 tees.

1. INTRODUCTION

This report documents a series of experimental elastic-response stress analyses and subsequent low-cycle fatigue-to-failure tests of five

*Southwest Research Institute.

†Mechanics Research Institute.

12-in. ANSI Standard B16.9 forged piping tees performed in support of the ORNL Piping Program.¹ The tests were conducted at Southwest Research Institute (SwRI), and the data were analyzed at Oak Ridge National Laboratory (ORNL). The material presented in this report was collected and summarized at Mechanics Research Institute (MRI).

The ANSI B16.9 tees are a class of commercially available butt-welding piping products fabricated in accordance with either the ANSI B16.9* or the MSS-SP48 manufacturing standard.^{2,3} These standards include dimensional and basic strength requirements for the fittings (piping products) as well as controls for certain other manufacturing variables. Fabricated fittings employing intersection welds, however, are considered as "pipe fabrication" and, as such, are specifically excluded.

In the design rules for nuclear piping systems, ANSI B16.9 tees are recognized as a class of piping products distinct from other types of tee joints. They are characterized by a smooth transition region† between the branch and run outlets and are normally formed from a segment of straight pipe using an external surface die and some means for extruding the branch outlet. Ratios of the outside diameter of the branch to the outside diameter of the run (d_o/D_o) lie within the range of approximately 1/3 to 1, because the manufacturing standards do not include dimensions for smaller reductions.

The objective of this investigation on ANSI B16.9 tees was essentially to provide sufficient baseline structural response-to-load information to evaluate and/or improve the adequacy of current design rules and criteria for nuclear power plant piping systems as defined in Sect. III, Div. 1, of the ASME Boiler and Pressure Vessel Code (hereinafter referred to as the Code).⁴ However, because of the fundamental nature of the investigations, the information obtained will be useful in a much broader range of piping system design applications.

*The American National Standards Institute (ANSI) was formerly the American Standards Association (ASA).

†Dimensional details describing the geometry of the transition region are not included in the standard, and it is only because of established practice of the major suppliers that we may claim that a smooth transition is characteristic of B16.9 tees.

Specifically, the objectives of the tests described in this report were to obtain sufficient experimental elastic stress-strain-deflection data and fatigue-to-failure results from each tee to make it possible to:

1. experimentally describe the elastic-stress distributions over the body of each tee for internal pressure and for a complete set of direct force and moment loading conditions (13 different loadings);
2. locate the maximum stresses and determine their magnitudes for each loading condition;
3. determine differences in stress distributions and magnitudes for nominally identical tees supplied by different manufacturers;
4. determine the relative importance of transverse shear force and bending moment loads on tees in a piping system;
5. provide experimental benchmark data for comparison with analytical solutions and photoelastic model studies;
6. determine experimental values for the stress indices and flexibility factors for individual and combined loading conditions for comparison with Code values; and
7. provide component fatigue-to-failure data for comparison with Code design criteria and analysis procedures.

The experimental stress analyses and low-cycle fatigue tests were performed at SwRI on the five 12-in. tees listed in Table 1.1, including two full-outlet sched-80 carbon steel tees, one full-outlet sched-160 stainless steel tee, and two reducing-outlet sched-40 stainless steel tees obtained from three different manufacturers as indicated. The tees were off-the-shelf products selected by the manufacturers to represent products that would normally be supplied to the builder of a nuclear power plant. When the tees were received, they were inspected, weighed, and measured in the ORNL Inspection Engineering Department. As far as could be determined, there was nothing unusual about the tees, which were, in fact, representative of "standard" products.

Plastic model replicas of the two sched-40 and two sched-80 tees were made in the Laboratory Division, Oak Ridge Gaseous Diffusion Plant, to provide hard model records of the shape of the tees and for uses such as laying out strain gages and demonstration. Attempts to make a plastic

Table 1.1. ORNL tee designations

Tee No.	Nominal size	Material ^a	Manufacturer
T-4	12 x 12 x 12 in. sched 80	C	I
T-6	12 x 12 x 12 in. sched 80	C	III
T-7	12 x 12 x 12 in. sched 160	SS	II
T-8	12 x 12 x 6 in. sched 40	SS	II
T-15	12 x 12 x 6 in. sched 40	SS	I

^aC = A106 Grade B carbon steel; SS = type 304L stainless steel.

model of the sched-160 tee were unsuccessful because of the heavier wall thickness and excessive shrinkage of the plastic during curing.

The tests were conducted at SwRI in accordance with Union Carbide Job Specifications JS-115-229 and JS-115-235, which are included in Appendix I. All the design, fabrication, and test work was conducted at SwRI in accordance with rather detailed instructions and guidelines specified by ORNL. Prior approval was required for all critical operations, including welding procedures and welder qualifications for the pipe-to-tee joints, strain-gage and dial indicator layout and placement, loading fixtures and application, strain-gage readings and data reduction, and loading conditions and operation of the fatigue tests. SwRI was responsible for the design and construction of the load frames, fabrication of the test assemblies, instrumentation and operation of the tests, reduction of the raw data to engineering strains and stresses, and transmittal of the data to ORNL for further evaluation and analysis.

Chapter 2 of this report includes a detailed description of the test setup and the test procedures used by SwRI. The series of tests performed on each tee included a preliminary brittle lacquer test to establish the adequacy of the strain-gage coverage, a series of elastic-response strain-gage tests, and a low-cycle fatigue-to-failure test. The bulk of the content of Chap. 2 was abstracted from SwRI test reports.⁵⁻⁹

Chapter 3 contains a complete discussion of the results from the elastic-response strain-gage tests. The elastic strain-gage data reduction and analysis procedure is described in Sect. 3.1. In general, the procedure was as follows. The computer code NOSEY¹⁰ was used to check the data for linear elastic behavior. Data points that deviated excessively from linearity were rejected, and appropriate notations were made in the computer program output. Stresses were then calculated and tabulated (in normalized form) from the data that passed the screening tests. Stresses calculated using strain data from gages where part of the data had been rejected were then checked by the analyst for anomalous behavior and adjusted if necessary. The adjustments were based on comparison with results from load cases and geometries known to give comparable stress solutions.

The final adjusted results from the elastic-response tests were then tabulated, summarized in the form of normalized stress intensities and experimental stress indices, and used to construct graphical contour plots for easier interpretation. Experimental values for the individual-load stress indices are tabulated and discussed in the body of the text. Because of the large amount of data obtained from the tests, the majority of these data are presented in the appendixes on microfiche at the end of the report for those readers needing benchmark information. Results from the initial data reduction, screened and tabulated by NOSEY, are given in Appendix VI. Listings of the final adjusted normalized stress intensities for each gage site and each load condition are given in Appendix VII. Comparable information is presented graphically in Appendix VIII. Materials given in Appendix VIII include plots of normalized stress intensity vs projected distance along strain-gage lines, stress intensity vs angular distance around the branch, and stress-intensity contour maps. Except for the contour maps, all the adjusted data points are identified in the figures. A representative set of the data (for internal pressure) given on microfiche in Appendixes VI, VII, and VIII is included in Chap. 3. Complete sets of dial indicator displacement data are given on microfiche in Appendix IX.

Results from the fatigue-to-failure tests are discussed in Chap. 4. The fatigue tests were intended to provide component failure data within the range of 500 to 100,000 cycles using the most severe applied bending mode (on the branch) as determined from the experimental stress analysis tests. The target failure point selected for all five tees was 7,000 fully reversed displacement-controlled bending cycles, which corresponds to the logarithmic mean between 500 and 100,000 cycles. The tests were run with a constant hydrostatic internal pressure equal to the maximum Code-allowable design pressure for the pipe extensions and a cyclic bending load based on the maximum stresses obtained from the experimental stress analyses. Failure was defined as a through-the-wall crack in the tee (or in one of the pipe-to-tee welds) as evidenced by a pressure leak. Results from the fatigue tests are tabulated and discussed in the text.

Results from both the elastic-response and fatigue tests, along with similar data from 24-in. ANSI B16.9 tees, will be used in a separate report to discuss the adequacy of current ASME Code procedures for the design of nuclear power plant piping systems.

2. TEST DESCRIPTION

The test work description given in this chapter is divided into three general categories: preparation of the test assemblies (models) and loading frames, performance of the static elastic-response tests, and performance of the low-cycle fatigue tests. Each subject is discussed in detail in the following sections.

2.1 Test Assembly and Loading Frame Preparation

General preparations for conducting the tests included fabrication of two test frames and construction and instrumentation of each of the test models. Each step was carried out as carefully and precisely as possible.

Logistics for testing the five tees listed earlier in Table 1.1 required setting up both the test facility and a separate facility for model fabrication. The test work was actually conducted at SwRI under two separate subcontracts, the first of which called for fabricating and testing four tees (T-4, T-6, T-8, and T-15) within one year. The experimental analysis for T-7 was added later under the second subcontract. The test program for each of the 5 tees was to include experimental stress analyses for 13 loading conditions and a low-cycle fatigue test to failure. To meet the time requirements, two test frames were constructed so that experimental stress analysis and fatigue testing could be conducted simultaneously. When all the experimental stress analyses were completed, both test frames were used for fatigue testing.

When it was decided to add T-7, the sched-160 tee, to the test program, work for the other tees had been in progress for nearly 10 months. The two test frames that had been constructed earlier were sufficiently oversized so that only minor modifications were needed to provide the higher loads required to test the heavier tee. However, there were other unique problems that had to be overcome. One of these was the unavailability of sched-160, type 304L stainless steel pipe because of long delivery quotations and minimum quantity requirements. Consequently, the T-7 test assembly was fabricated using 6-in.-long stainless steel pipe stubs welded to the tee, with the remainder of the branch and run pipe

extensions fabricated from carbon steel pipe. The 6-in.-long pipe stubs (also needed for other reasons described later) were made from 1.5-in.-thick, type 304L stainless steel plate. There was a sufficient quantity of this material on hand at SwRI to fabricate five 6-in.-long pipe stubs, two of which were used to qualify the welder and welding procedures. Full details of the fabrication and testing schedule are given in Appendix II. In some cases it was possible to carry out some of the tasks simultaneously.

2.1.1 Strain-gage layout

A general scheme was established for strain-gage layout that would give ample coverage of two quadrants of each tee with matching gages on the inside and outside surfaces to determine the maximum stresses for any one of the 13 different loading conditions and for both the membrane and bending stress distributions. Particular attention was given to the instrumentation of the branch-run transition region and to the problem of locating gages on the inside surface "back to back" with the gages on the outside.

Two terms must be defined here to adequately describe the gage layout. The term "crotch line" is used to denote a line lying along the approximate root of the transition region between the branch and run of the tee. The term "gage line," or " ϕ line," is used to denote a line on the outside surface of the tee formed by the intersection of a diametrical plane through the branch at an angle of ϕ degrees from the longitudinal plane of the tee. At the crotch line, the gage line changes direction so that it intersects circumferential lines on the run at an angle of $\psi = (90 - \phi)$ degrees, as shown schematically in Fig. 2.1. For each tee, gage lines were located in the $\phi = 0^\circ$ to 90° quadrant and in the 180° to 270° quadrant at 22.5° intervals. Ten three-gage strain rosettes were spaced more or less uniformly along each gage line with one of the rosettes always located on the intersection of the ϕ line with the crotch line. The crotch line was also instrumented with an extra rosette midway between each ϕ line. Isometric views of the gage layout for the 0° to 90° quadrant of the full-outlet tee T-4 and the reducing-outlet tee T-15 are shown

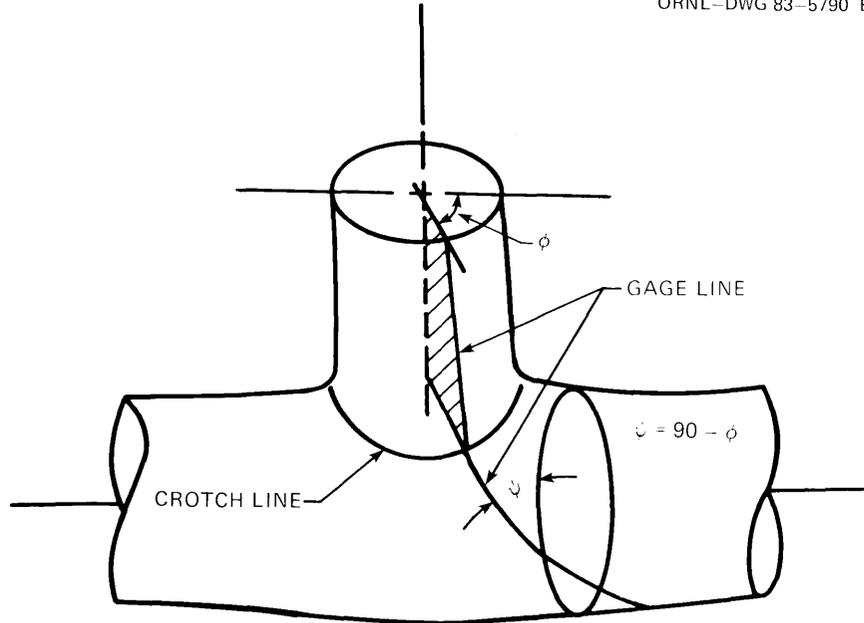

Fig. 2.1. Strain-gage line nomenclature.

in Figs. 2.2 and 2.3, respectively. A complete set for each tee is given in Appendix III.

Strain-gage positions for the inside surface were located by passing a line through each outside gage position normal to the midplane of the shell (tee). For the models containing T-4, T-6, T-8, and T-15, cross sections of the tee at the $0^\circ \phi$ line and the $45^\circ \phi$ line were outlined by sectioning plastic models of the respective tees. For T-7, the cross sections at the $0^\circ \phi$ line and the $45^\circ \phi$ line were outlined by trimming cardboard until a good fit was obtained on the inside and outside surfaces and then spacing the cardboard pieces to match thickness measurements on the cylinder walls. Although this procedure gave adequate results, a plastic model would have made the job easier. This procedure was necessary to establish the "normal to the midplane" in the crotch area where the geometry was too complicated to be treated analytically.

After the strain-gage positions were determined, their locations were measured in three-dimensional XYZ coordinates and recorded. These "exact" locations are given for each tee in Appendix III. For accurate determination of the XYZ coordinates at each gage site, the tees were placed on a precision plane table, as shown in Fig. 2.4, and the elevation of each

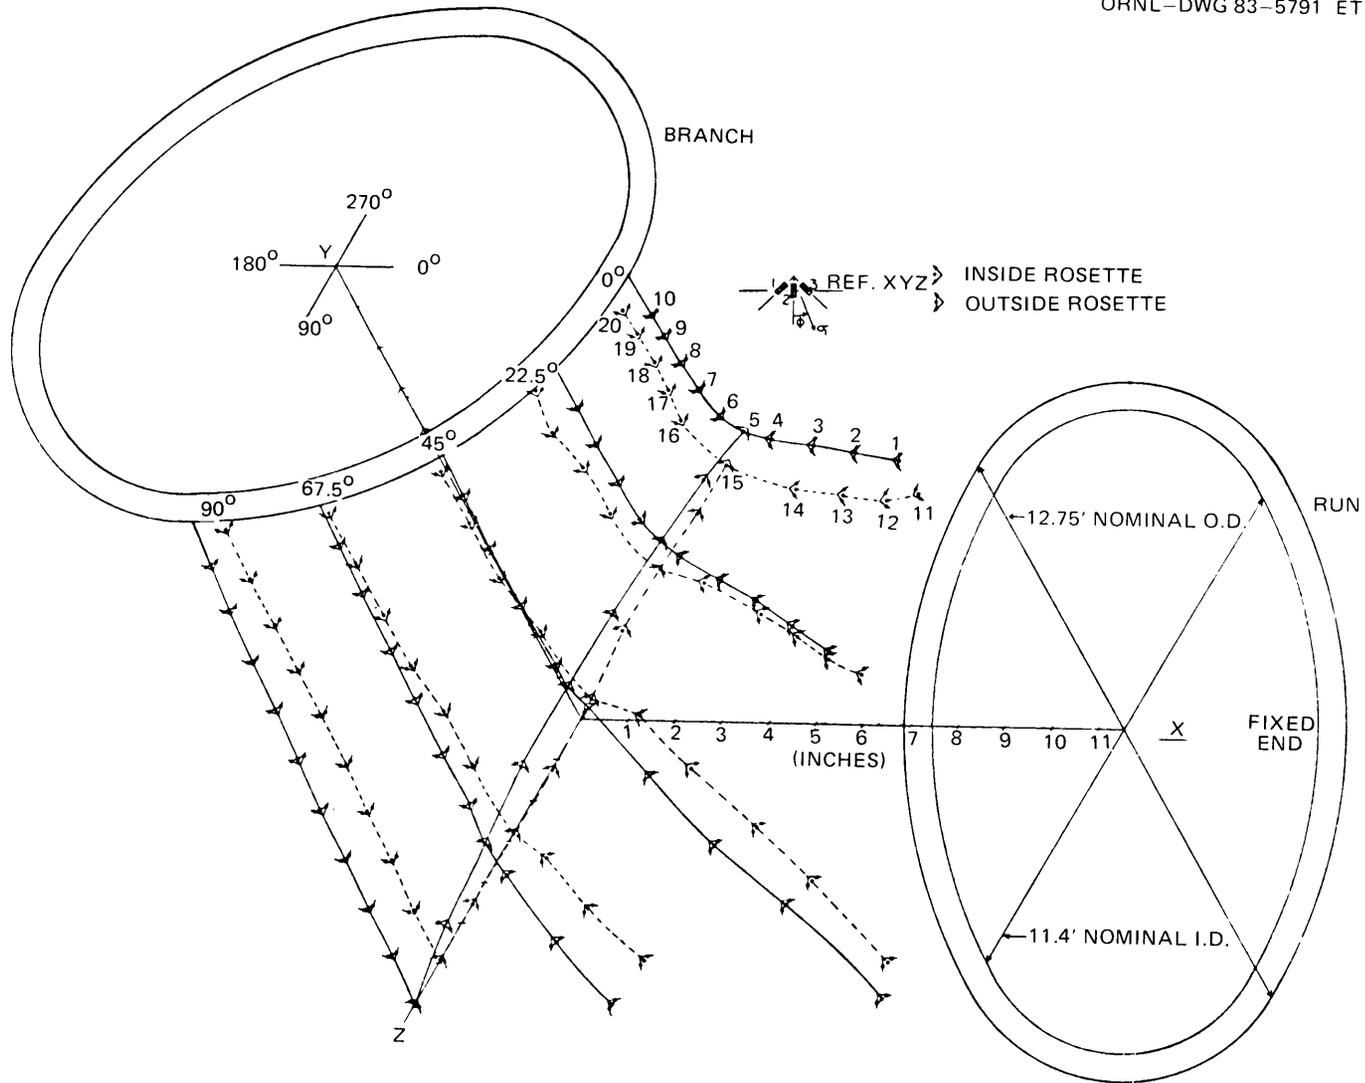

Fig. 2.2. Strain-gage rosette locations for 0° to 90° quadrant of T-4.

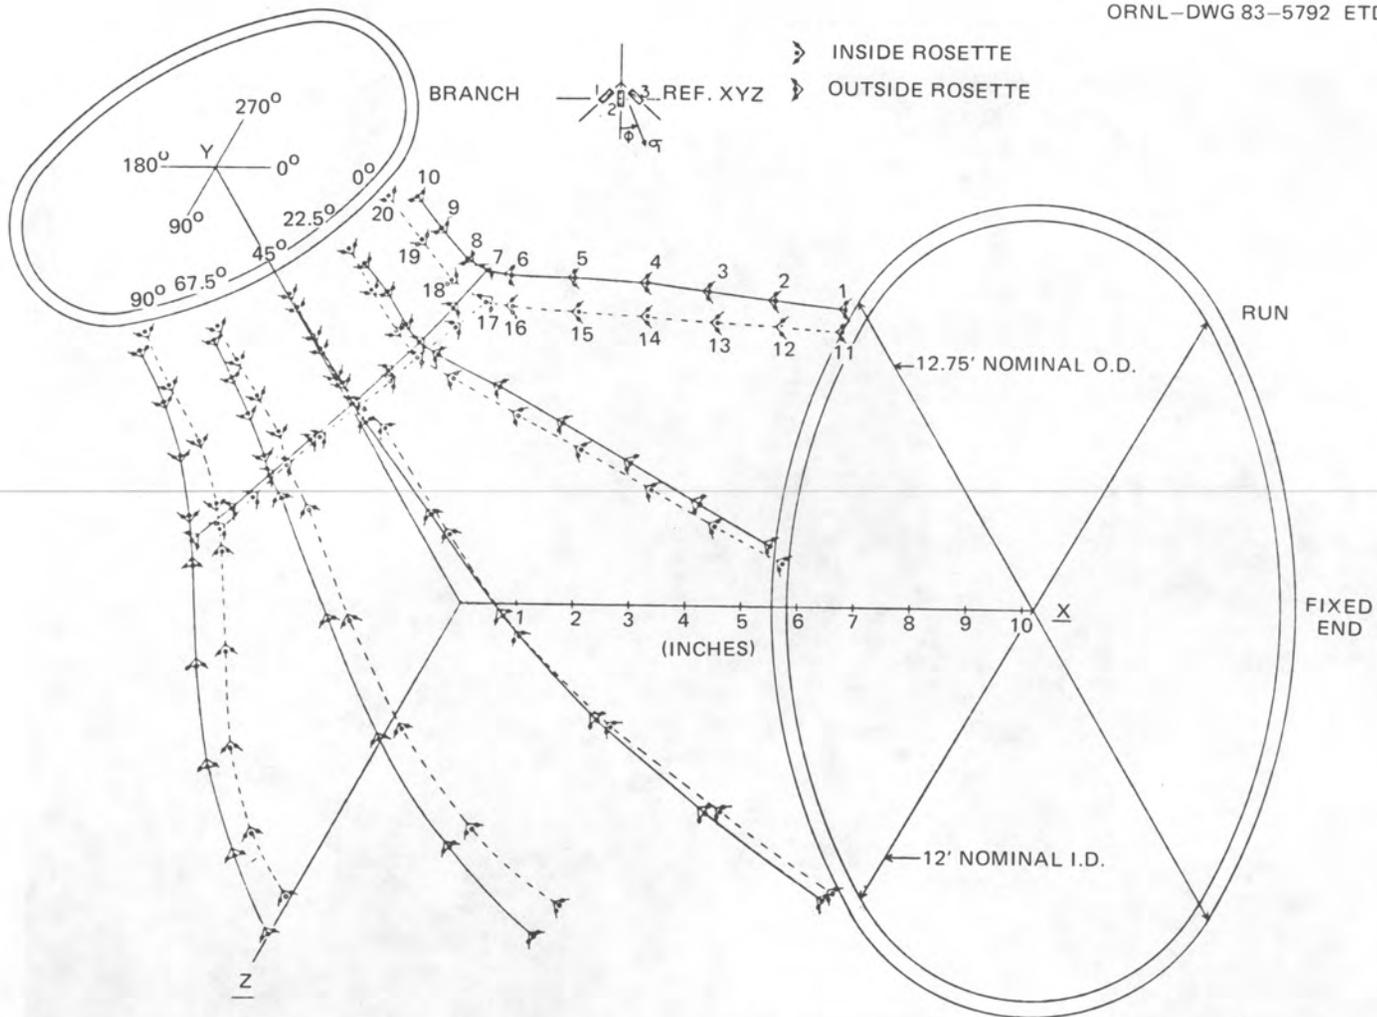

Fig. 2.3. Strain-gage rosette locations for 0° to 90° quadrant of T-15.

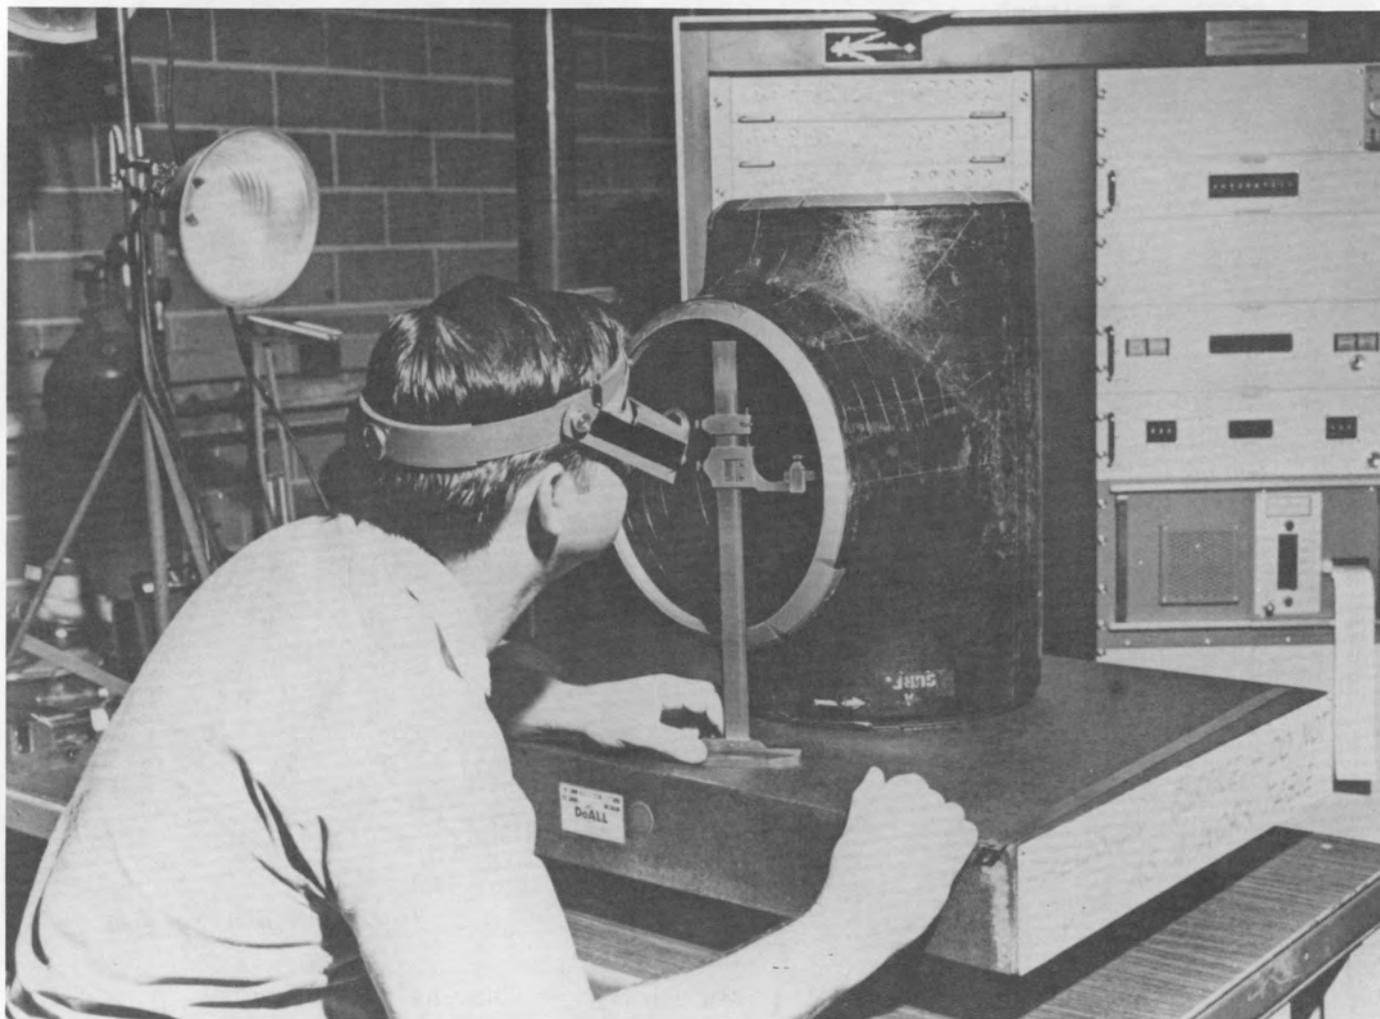

Fig. 2.4. Determination of XYZ coordinates of strain-gage rosette locations on a B16.9 tee.

gage position was measured relative to a reference point on the tee with a vernier height gage. A simple but time-consuming procedure accurately located the rosettes on the inside surface relative to those on the outside surface and also established the XYZ coordinates. Reference marks at 0° , 90° , 180° , and 270° around the branch outlet plus three marks in a straight line across the bottom, as shown in Fig. 2.5, had previously been stamped on the tees. Combinations of these seven reference points were used to define planes passing through the intersection of the axes of the branch and run.

The strain-gage rosettes used throughout the test program were Micro-Measurement type EA-06-062RP-120, option W for the carbon steel tees (T-4 and T-6) and type EA-09-062RP-120, option W for the stainless steel tees (T-7, T-8, T-15). Each strain rosette consists of three 1/16-in.-long temperature-compensated gages oriented at 45° angles and numbered counter-clockwise (for these tests). Gage 2 (the center gage) was positioned to measure strain in the direction of the ϕ line or the crotch line on which

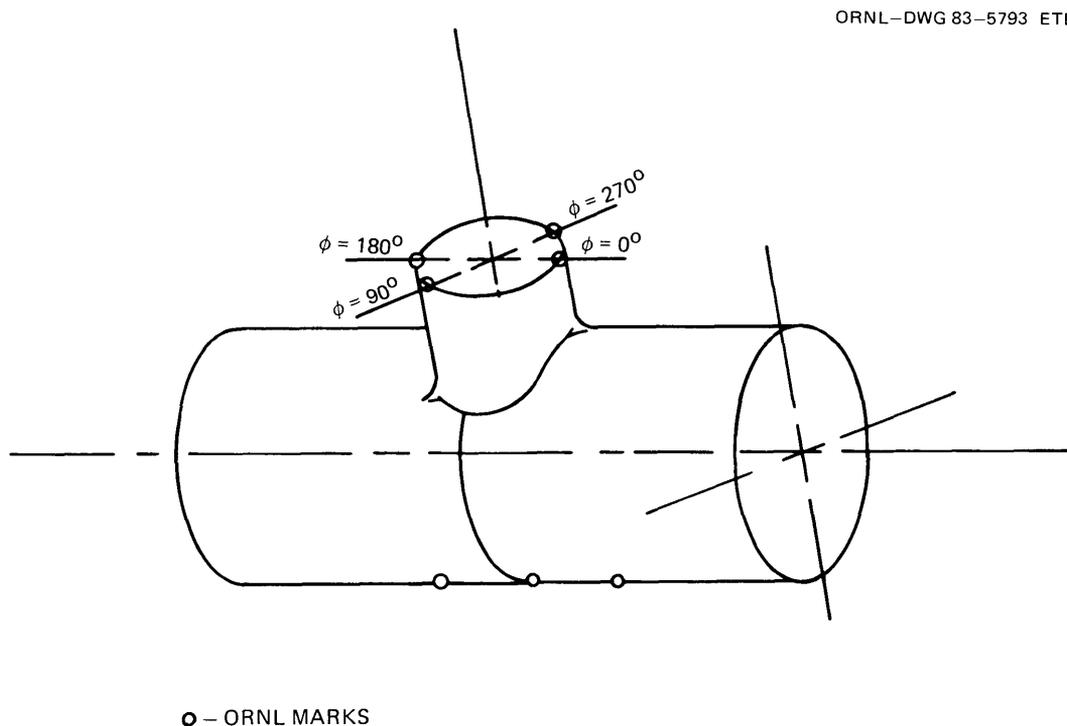

Fig. 2.5. Location of marks used for identifying reference planes.

it was placed. The gages were bonded to the surface with Eastman 910 cement. The XYZ coordinates for each rosette are referenced to the center of gage 2.

The direction of the principal stresses that are presented later in this report is given relative to the direction of gage 2 (i.e., along a ϕ line or crotch line) with a positive angle being counterclockwise. The orientation, the numbering system used for identification, and the XYZ coordinates of each rosette are given for all five tees in Appendix III. Photographs of the gage installation (both inside and outside) in the 0° to 90° quadrant of T-4 are shown in Fig. 2.6. As a final check on the accuracy of the strain-gage locations, a set of computer plots was made for each tee using the reported coordinates as input. On the basis of the results of this computer check, a few minor adjustments in the recorded gage positions were made.

2.1.2 Test model fabrication

Each test assembly consisted of a 12-in. NPS forged ANSI B16.9 piping tee, three pieces of 54-in.-long pipe, three 6-in.-long pipe stubs, and three 1-ft² by 3/4-in.-thick carbon steel plates for end fixtures to which loads could be applied. Except for the end plates, the models containing T-4 and T-6 were made entirely of sched-80 A106 Grade B carbon steel, and the T-8 and T-15 models were made entirely of sched-40 type 304L stainless steel. As mentioned earlier, the 54-in. pipes used in the T-7 model were made of sched-160 A106 Grade B carbon steel. Because T-4, T-6, and T-7 are full-outlet tees, 12-in. pipe was used for the branch as well as for the run pipe extensions. The minimum and maximum inside diameters, outside diameters, wall thicknesses, and the weights of the 6-in. pipe stubs are presented in Table 2.1. Also given are the weights of the tees before and after welding and grinding had been completed. Table 2.2 gives the corresponding ANSI B36.10 standard nominal dimensions and section properties of the branch and run pipe extensions.^{11,12}

The fabrication of the model had to be performed in a manner that would permit the installation of strain gages on the inside surface of the tee and on the pipe-to-tee weldment. According to the test specifications, the pipe-to-tee weld was to be ground flush with the pipe surface

in order to install strain gages at the weld joints and to ensure that no discontinuity would remain that might cause a fatigue crack to be initiated prematurely during the fatigue test. To accomplish these objectives, 6-in.-long pipe stubs were welded to the tee. These extensions permitted access to the inside surface of the tee for strain-gage installation and grinding. They also removed the pipe-to-pipe weld far enough from the gages so that, with minimum care, the instrumentation would not be damaged by the heat from welding.

Exceptional weld quality was specified for the pipe-to-tee weldment to minimize the possibility of a fatigue crack initiating at the weld rather than in the tee during the low-cycle fatigue test. The procedures for welding and nondestructive inspection developed to meet these requirements are presented in Appendix IV. Note in the welding procedures that the metal preparation conforms with Fig. NB-4250-1 of the Code.⁴ A welder was successfully qualified using these acceptance criteria and welding procedures, and nondestructive inspections of the pipe-to-tee weldments were performed prior to the strain-gage installation. A photograph of T-8 during the tungsten-inert gas (TIG) welding is shown in Fig. 2.7.

After the 6-in.-long pipe stubs were attached, the tee was placed on the precision plane table so that XYZ coordinates for the gage locations on the pipe-to-tee weldment could be determined. Strain gages were then installed on the inside surface of the tee. When this was completed, the 4.5-ft-long pipe legs were welded to the tee, and the loading fixtures were welded to the pipe. Care was taken to keep the interpass temperature of the pipe-to-pipe weld down to prevent damage to the strain gages. The temperature of the pipe stub 3 in. from the weld was checked after each welding pass with a Tempilstik wax pencil and was not allowed to exceed 250°F.

2.1.3 Test setup

The model was installed for testing in a large test frame specifically designed and constructed for this program. The 12 moment, shear, and thrust loads that were to be applied are shown schematically in Fig. 2.8. It should be noted that for these loading cases one end of the run was fixed (i.e., bolted to the load frame), while the branch and the other end of the run were free. The loads were applied one at a time to either the branch or the free end of the run with the model supported only at the fixed end. For the internal-pressure case, the model was fixed at the load frame, and the free end was supported by bearings to counteract the weight of the pressurizing fluid.

The test frame was designed so that 8-in.-bore, 12-in.-stroke hydraulic jacks could be bolted in the various positions required to apply torsion, bending, thrust, and in-plane shear loads. Hydraulic jacks with a

Fig. 2.7. T-8 during TIG welding of third pipe stub.

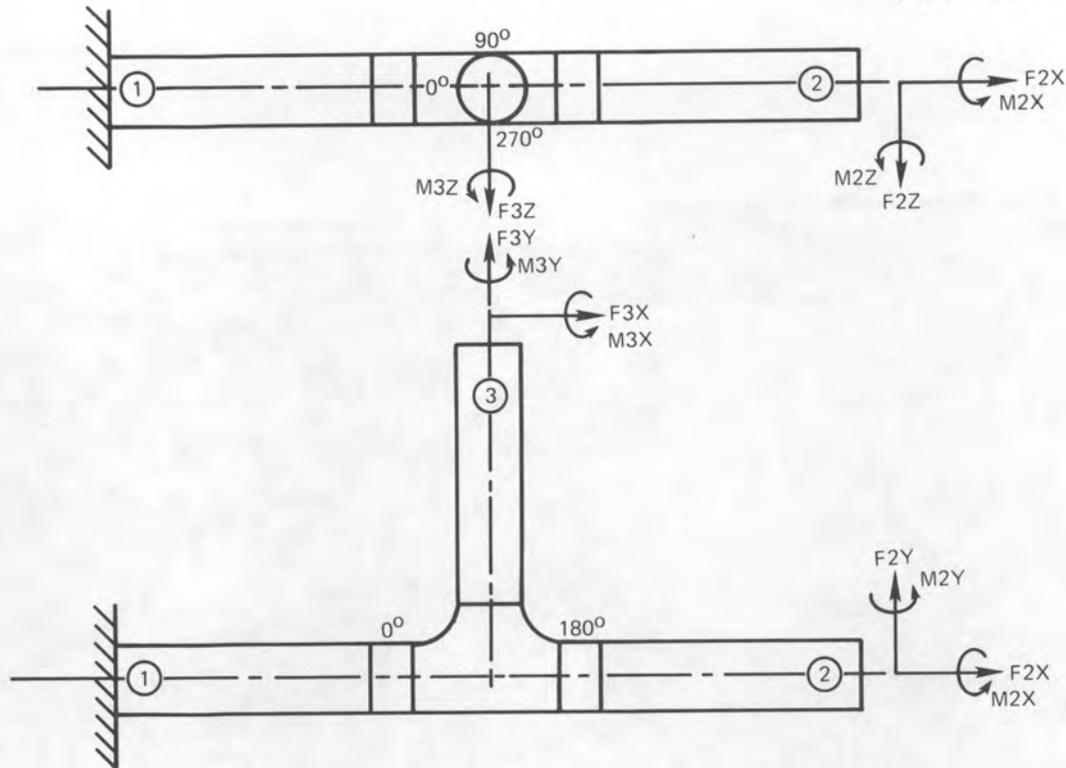

Fig. 2.8. Loading nomenclature (all loads positive as shown).

5-in. bore and 12-in. stroke were used to apply the out-of-plane shear loads. Figure 2.9 shows T-4 in place with two hydraulic jacks set up for applying out-of-plane bending on the branch (load case M3X). The channel above the fixed end of the run contains the hole pattern where the hydraulic jacks were attached to apply either the torsion (M3Y) or in-plane shear (F3X) loads.

A moment-couple was applied to the end of the branch or run for the bending- and torsion-load cases. Because the piston area was smaller on the side of the piston rod, a higher pressure was applied to the jack that was "pulling" than was applied to the jack that was "pushing" to achieve equal and opposite loads. During operation of the tests, two technicians were required to manually control the two high-pressure needle valves in order to carefully maintain a constant load on the model while a third technician recorded the data. For the direct-force-load cases, the loads could be applied using the same pressure level for both hydraulic jacks; consequently, only two technicians were required.

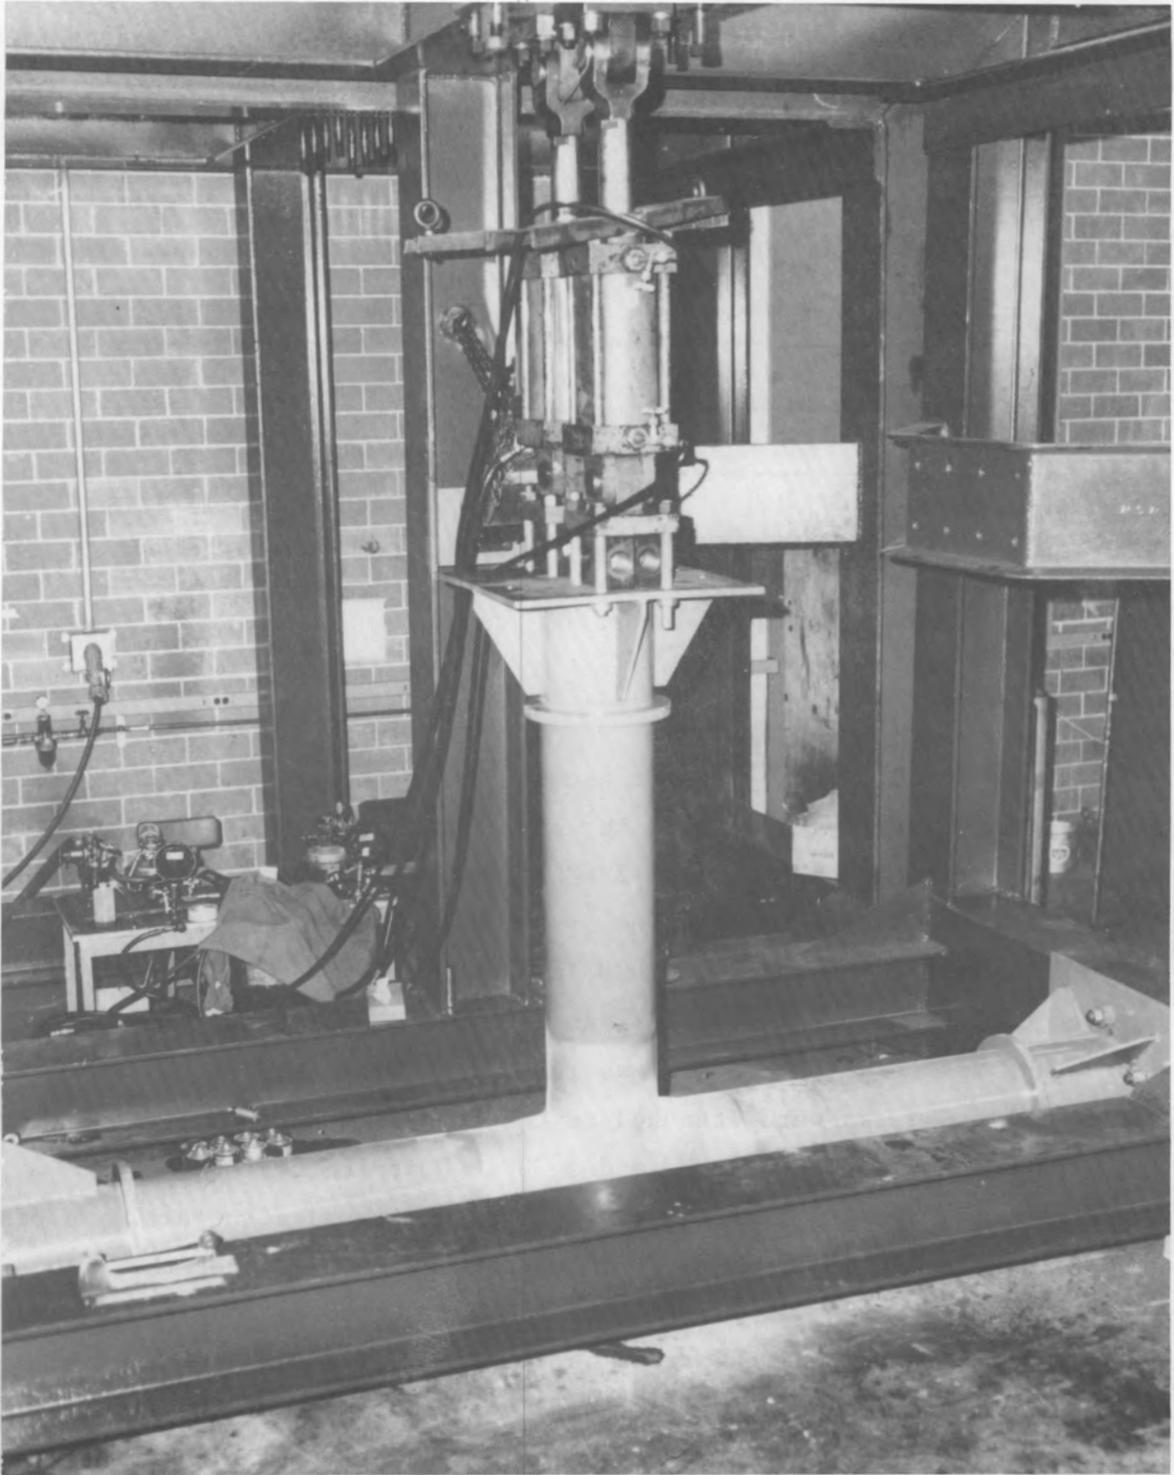

Fig. 2.9. T-4 prior to brittle coating analysis.

The location of the shear vector for applying the transverse-force loads F2X, F2Z, F3X, and F3Z was determined by the position of the hydraulic jack attachments, as shown in Fig. 2.9 for T-4. The distance of these vectors from the center of each tee is given in Table 2.3.

Table 2.3. Distance "L" of the transverse shear vectors from the center of each tee^a

Moment arm	Tee No.				
	T-4	T-6	T-7	T-8	T-15
Branch (L_b)	77-1/8	79-3/8	77-13/16	77-3/8	76-3/16
Run (L_r)	77-7/8	77-7/8	78-7/8	77-7/8	77-7/8

^aDistances are in inches.

To accommodate the hydraulic jacks and tee models, the overall dimensions of the test frames were 25 ft long x 13.5 ft high x 7 ft wide. The main load-carrying members were 12 WF 85 beams. Approximately 19 tons of steel was used in each frame. The frames were capable of withstanding 500,000 lb in the F2X mode, 200,000 lb in the F3Y mode, 300,000 ft-lb in bending, 200,000 ft-lb in torsion, and 100,000 lb in shear. The loading frame that was used to test T-7 was reinforced at the positions where the torsional-load jacks were attached to the frame. With this modification, the structure was able to withstand a 300,000 ft-lb torsional load — a 100,000 ft-lb capacity increase over the unreinforced structure. No other changes were made for the T-7 tests. A photograph of one of the test frames is shown in Fig. 2.10; fabrication had just been completed when the photograph was made, and the frame is lying on its side.

For each load case, displacements (and rotations) of the pipe extensions were measured for use in determining flexibility factors. Displacements were measured using circular dial indicators, accurate to the nearest 0.0005 in. A sketch of the mounting frame for the dial indicators on T-7 may be seen in Fig. 2.11. Similar figures for the dial indicator

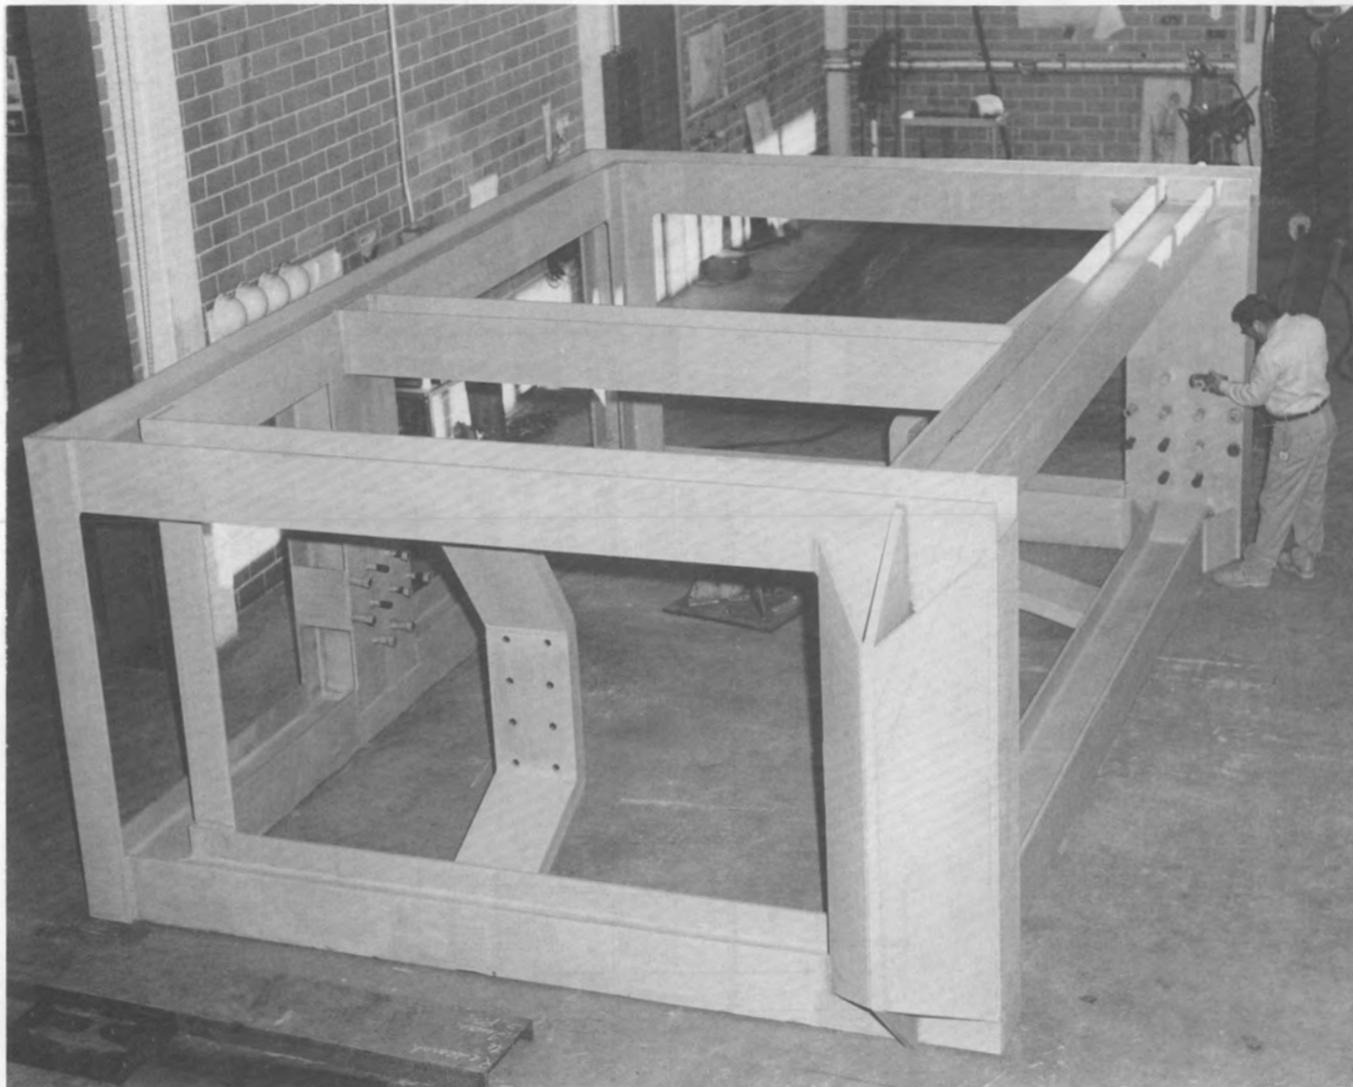

Fig. 2.10. Load frame for testing 12-in. NPS ANSI Standard B16.9 tees.

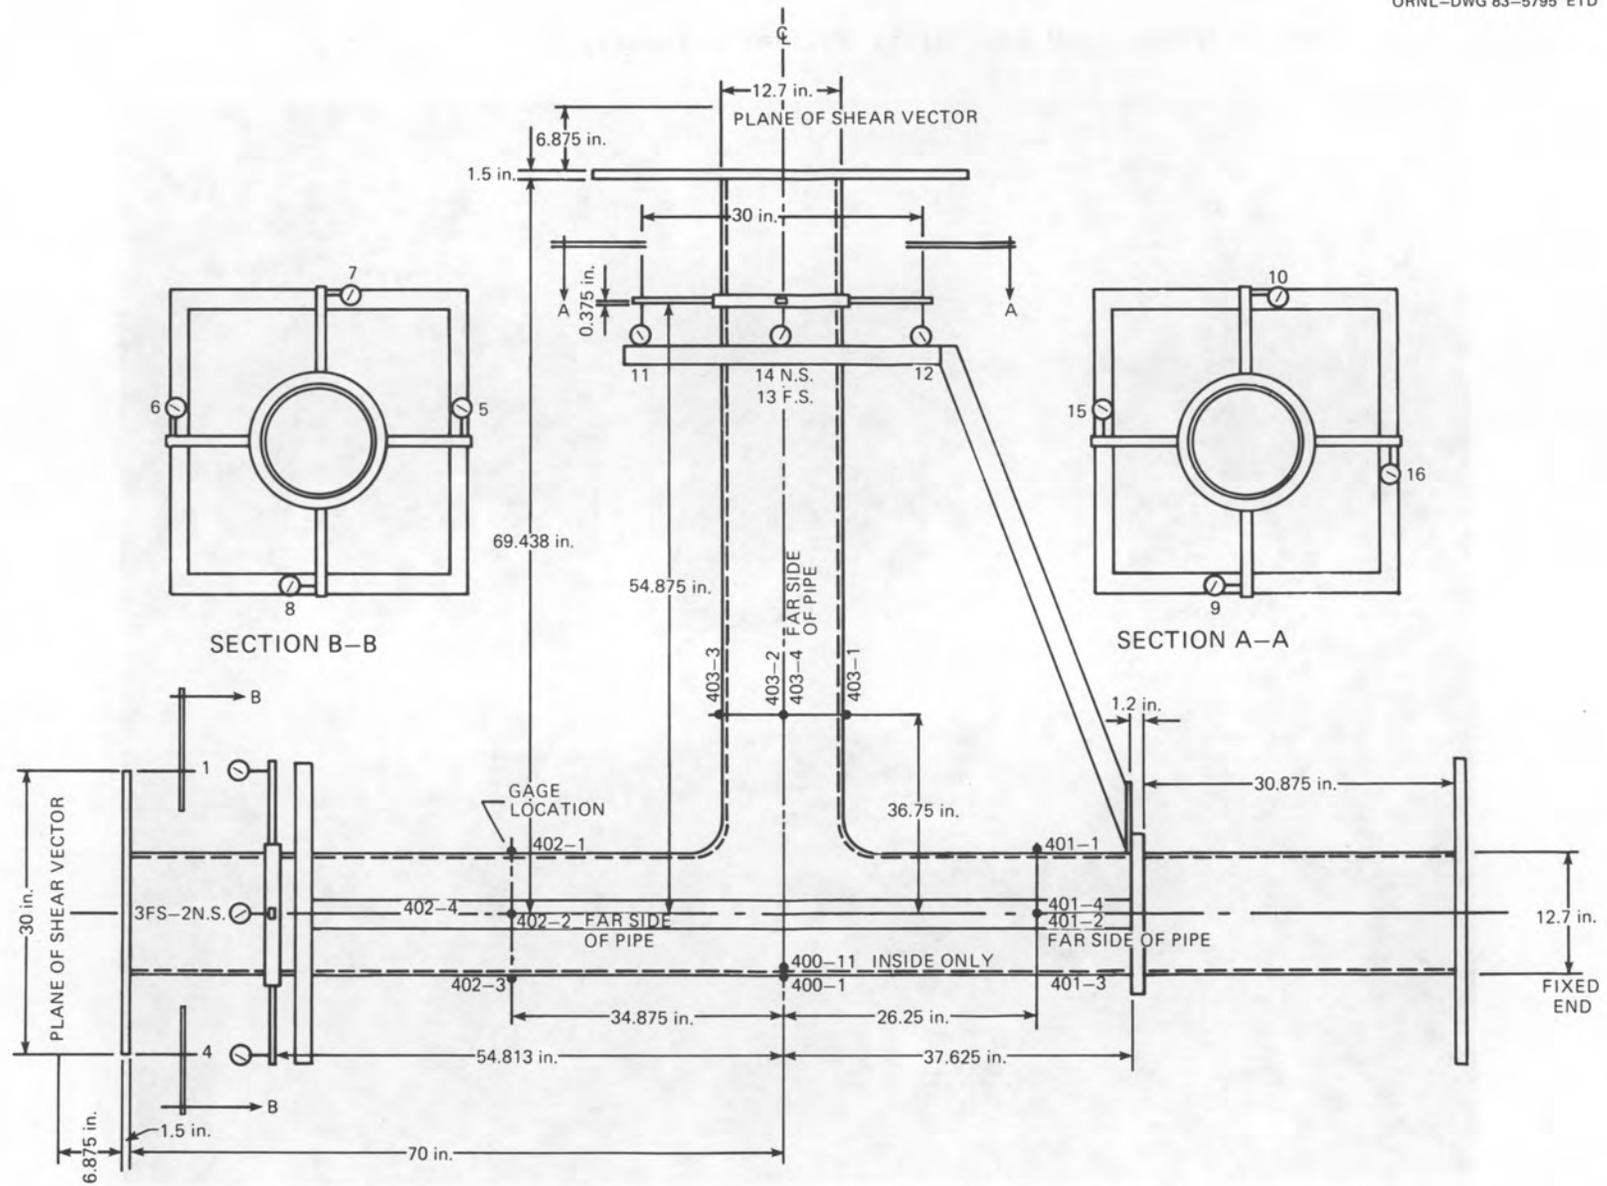

Fig. 2.11. Location of dial indicators and pipe-leg rosettes for T-7.

frames for all five tees are given in Appendix IX. Note that the dial indicator frame is mounted only at the steel ring near the fixed end so that all deflections were measured relative to a point on the model. Sixteen dial indicators were monitored. The numbering system used for the dial indicators, their exact locations, and the location of the point at which the mounting frame is attached to the model are also shown in Fig. 2.11. The dial indicators were carefully and consistently mounted with their pointers 15 in. from the center of the pipe. A template was used to locate these instruments in lieu of measuring from the outside surface of the pipe. Dial indicator readings were, of course, obtained manually and are listed in Appendix IX.

Strain-gage rosettes were also mounted on the three pipe legs of the model to monitor the loads. Figure 2.11 shows the location and identification of these rosettes for T-7. Note that two additional rosettes were mounted on the bottom of the tee on both the inside and outside surfaces. The rosette locations on the pipe legs and on the bottom of the tee were given a 400 series designation (i.e., 400-1, 401-2) to distinguish them from rosettes in the main array on the tee.

The strain-gage data were recorded on a B & F Model SY 156 data acquisition system. To speed up reduction of the data, a high-speed paper-tape punch was installed on the B & F so that data were simultaneously printed on adding-machine-type paper and punched on teletype paper tape. The printer information was used for on-line review of the strain data and for the permanent record. The teletype paper tape was fed into an IBM paper-tape-to-card converter, which quickly transferred the data to IBM cards.

The data acquisition system was only capable of handling 100 strain gages at one time, recording data at a rate of five channels per second, and printing gage readings directly in strain to the nearest microinch per inch. Because each model contained 681 individual strain gages, it was necessary to perform the test for each load condition seven times to obtain a complete set of data.

The tests were conducted in an air-conditioned laboratory where the temperature is maintained at 75°F. The temperature normally does not fluctuate more than $\pm 2^\circ\text{F}$ there, except when large doors are opened once or

twice each day to transfer large equipment. The doors do not remain open more than a few minutes at a time, and the air-conditioning system returns the laboratory temperature to normal within 15 min after the doors are shut. Because the strain gages and wiring were temperature compensated, these occasional temperature fluctuations were not expected to cause apparent readings of more than $\pm 5 \mu\text{in./in.}$ During the early part of the testing program, however, NOSEY analysis of the data indicated that the effects of temperature variations could be detected. Therefore, the tests were rerun with the laboratory doors kept closed, and the doors were not opened during all the subsequent tests.

2.2 Static Load Test Procedure

Two experimental stress analysis techniques were used in carrying out the static load test portions of the program. The first was a qualitative test using a brittle lacquer coating to determine if the outside strain-gage layout was adequate. The second was a quantitative test during which data were acquired from electrical resistance strain gages located on two quadrants of the tee and dial indicators located on the branch and run of the test model.

The brittle lacquer tests were performed on all tees except T-6 and T-15. Because T-6 and T-15 were nominally the same as T-4 and T-8, respectively, it was felt that no new information would be obtained by duplicating these efforts. A general description of these tests is given in the following paragraphs. A more detailed discussion of the test results is given in Appendix V.

The quantitative tests were performed on each tee and constituted the primary portion of the static load test program. The procedure followed in performing these tests is described in Sect. 2.2.2.

2.2.1 Investigation of strain-gage layout adequacy

The brittle coating test was performed on T-4, T-7, and T-8 primarily to determine if the strain-gage layout was adequate. For these tests, a Stresscoat-brand brittle lacquer was sprayed on the outer surface of the tee. The lacquer sensitivity was $450 \mu\text{in./in.}$ for the T-4 test and

600 $\mu\text{in./in.}$ for the other two tees. Several different loads were applied to each tee starting with an out-of-plane bending load on the branch (M3X), because it was expected that this loading would produce the highest stresses. The loads were applied until cracking was observed, and photographs were taken before moving to the next load condition.

Out-of-plane bending loads were applied to the branch in small increments to a maximum load of 41,000 ft-lb on T-4, 100,000 ft-lb on T-7, and 14,000 ft-lb on T-8. An out-of-plane shear load was applied in the same manner to a maximum of 12,000 lb for T-4, 20,000 lb for T-7, and 12,000 lb for T-8. The out-of-plane shear force (F3Z) was applied in a direction that gave an effective bending moment (M3X) with an opposite sign from that of the applied moment tests indicated in Fig. 2.8. The T-4 tests also included application of out-of-plane bending and shear loads (M2Y and F2Z) on the run pipe. These loads were not applied to T-7 and T-8 during the brittle lacquer tests.

An evaluation of the results of each test showed that the strain-gage coverage was adequate. Photographs and significant comments relative to the brittle lacquer tests are presented in Appendix V.

2.2.2 Elastic load tests

Following completion of the brittle coating tests for each tee and subsequent review of the test data, strain gages were installed on the external surface of the tees. These gages, together with the gages previously installed on the internal surface, and the dial indicators constituted the primary sources of data for the elastic load tests.

The elastic load tests performed on each tee consisted of a series of 13 load conditions as illustrated schematically in Fig. 2.8. Prior to any of the tests, a loading schedule was established to limit the maximum load for any load condition to a value that would generate a nominal stress of 20,000 psi in the pipe. The maximum load that was actually applied, however, was limited by the requirement that strains not exceed 1000 $\mu\text{in./in.}$ during any test to preclude the possibility of inadvertent yielding. The scheduled loads and the maximum loads that were applied are given in Table 2.4. Each loading was applied to one-half of the programmed maximum load, and then the strain gages were read. If the readings showed that

^aBased on a nominal pipe stress of 20 ksi in the pipe.

^bNeeded to attain a maximum strain on the tee near 1000 $\mu\text{in./in.}$

^cLimited by the maximum stress in the pipe at the fixed end.

the strain would exceed the upper limit of 1000 $\mu\text{in./in.}$, the maximum load was adjusted accordingly. After determining the allowable maximum load for a particular load condition, the tee was loaded to the maximum load and unloaded until linear elastic behavior was observed. For most of the gages, linear elastic response was attained on the first cycle. Three cycles were applied for good measure because only the gages in the high-stress regions were actually monitored during the test.

Figure 2.12 shows T-7 in the loading frame during the experimental stress analysis. Two hydraulic jacks are set up for applying either a torsional moment M3Y or an in-plane transverse force F3X on the branch. The loading clevises for applying out-of-plane bending M3X or axial thrust F3Y on the branch can be seen in the upper part of the photograph.

When recording data, the tees were loaded in four incremental steps to the maximum load. The steps were then repeated during unloading, giving a total of nine strain readings for each gage for each load case. These data were recorded and retained for later use. Two runs were made for each loading condition, and the data were reviewed before going on to the next loading condition.

As noted earlier, the strain data were recorded on a B & F Model SY 156 data acquisition system equipped with a high-speed paper-tape punch. An IBM paper-tape-to-card converter transferred the data to IBM cards, and the data were reviewed at SwRI using the computer program NOSEY before the cards were sent to ORNL for more extensive analysis. Destructive fatigue tests were not started until after it had been established that the strain-gage tests were satisfactory and that all the required elastic-response data had been obtained.

2.3 Fatigue Test Procedure

The procedure planned for the fatigue tests was to select the branch-pipe bending mode that produced the highest stress index in the tee and then to estimate the magnitude of the load that would cause failure in ~ 7000 cycles of completely reversed displacement. The target value of 7,000 cycles is the logarithmic mean of 500 and 10^5 cycles, and for carbon steel, corresponds to a maximum equivalent elastic-stress amplitude of

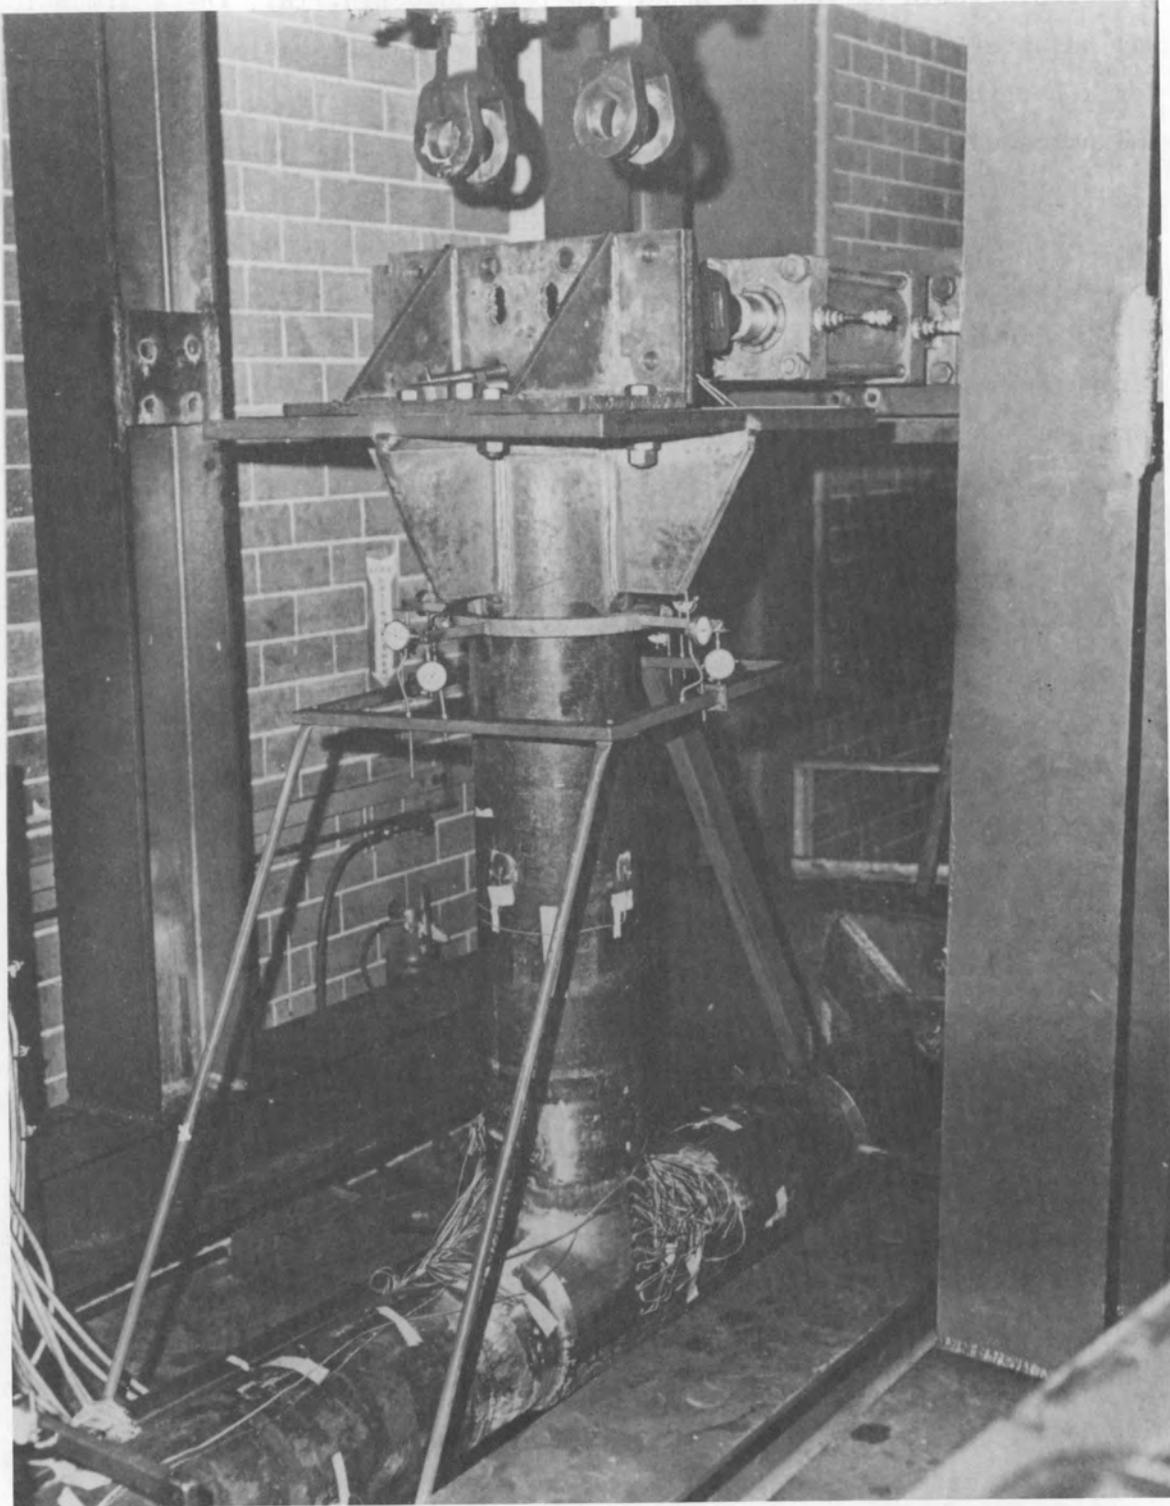

Fig. 2.12. T-7 in loading frame for experimental stress analysis.

~83,400 psi. During the fatigue tests, the internal pressure was maintained at the maximum design pressure of 1925 psig for T-4 and T-6, 3240 psig for T-7, and 950 psig for T-8 and T-15, all of which were calculated in accordance with the Code-allowable pressure equations of NB-3641.1, using 85% of the nominal wall thickness, i.e.,

$$p = \frac{2 S_m t}{D_o - 0.8t} , \quad (2.1)$$

where

$$t = 0.85t_{nom},$$

S_m = Code design stress intensity.

At the time these fatigue tests were being performed, the simplified elastic-plastic analysis method now contained in paragraph NB-3653.6 of the ASME Code was not available. Therefore, to select a loading that would give fatigue failure data for stress ranges exceeding twice the yield strength (or $3 S_m$), Markl's empirical fatigue-life relationship^{13,14} for piping components was extrapolated into the low-cycle range. For carbon steel, the relationship is

$$S_a = 490,000 N^{-0.2} ,$$

where

S_a = alternating stress,

N = number of cycles to failure.

Remember that the fatigue tests were not performed to investigate the adequacy of this equation. Rather, the equation served only a supporting role in that it was used to identify stress ranges that would cause the models to fail in a reasonable number of cycles. Also note that, although Markl's relationship was used to form the basis for some of the fatigue analysis procedures of the ASME Code, it is not used directly in the more current editions.

An alternating out-of-plane shear load on the branch (F3Z) was selected for T-4, T-6, T-8, and T-15 based on results from the elastic-response tests, while an in-plane shear load on the branch (F3X) was used

for T-7. For each load case, the stress data were scanned to find the rosette at which the highest stress-to-load ratio occurred. Table 2.5 summarizes these ratios and the resulting initial fatigue load amplitudes. For those models where more than one gage is listed, the first gage in the list corresponds to the location of the maximum stress-to-load ratio, and the other gages listed gave ratios almost as high. All the gages listed were considered potential sites for fatigue failure.

Because the minimum allowable yield strength of A106b Grade B carbon steel (T-4 and T-6) is 35,000 psi and that of type 304L stainless steel (T-7, T-8, and T-15) is 30,000 psi, a stress value of 83,400 psi is fictitious because local plastic deformation will occur before this value is reached. The value of 83,400 psi is based on empirical fatigue data that is presented in the Code as equivalent elastic stress vs cycles to failure, where the stress values are assumed to be proportional to the strains.

A constant maximum displacement was maintained during the fatigue test instead of a constant maximum load to better simulate the type of loading that would occur in a piping system. The experimental procedure used to establish the limiting branch pipe displacements was as follows. A dial gage was mounted on a reference frame to measure the displacements of the branch pipe at an arbitrary point about 3 ft below the loading fixture, as shown in Fig. 2.13. A linear load-displacement relation was then established by loading the test assembly in the appropriate fatigue testing mode in small increments well within the linear elastic-response range. The strain-gage rosette identified earlier as giving the maximum stress-to-load ratio was also read at each loading increment. The linear load-displacement and load-strain relations were then extrapolated to the appropriate load value (Table 2.5). The corresponding displacement was determined, and the cycling facility was set to maintain this displacement. The load was then fully reversed so that the maximum displacements in both directions were determined prior to applying the full load in either direction. Microswitches were mounted on each side of the branch in line with the shear vector. A screw adjustment on one of the microswitches was slowly turned while the proper dial indicator reading was maintained. When the microswitch was tripped, the load was reversed. The

Table 2.5. Gage locations for maximum alternating stresses and corresponding fatigue test loads

Model	Strain gage	Load direction	Stress/load ratio (ksi/1000 lb)	Alternating load amplitude (lb)	Alternating elastic-stress amplitude (psi)	Constant internal pressure (psig)
T-4	67-05	±F3Z	2.77	30,000	±83,100	1,925
T-6	56-01, 45-05, -06, -07, 67-05, -06, -07	±F3Z	2.833	29,460	±83,460	1,925

T-15	270-07, 67-05, -06, -07; 78-01, 90-05, -06, -07, -08, 247-05, -06, -07; 258-01 270-06	±F3Z	19.892	4,255	±84,640	950

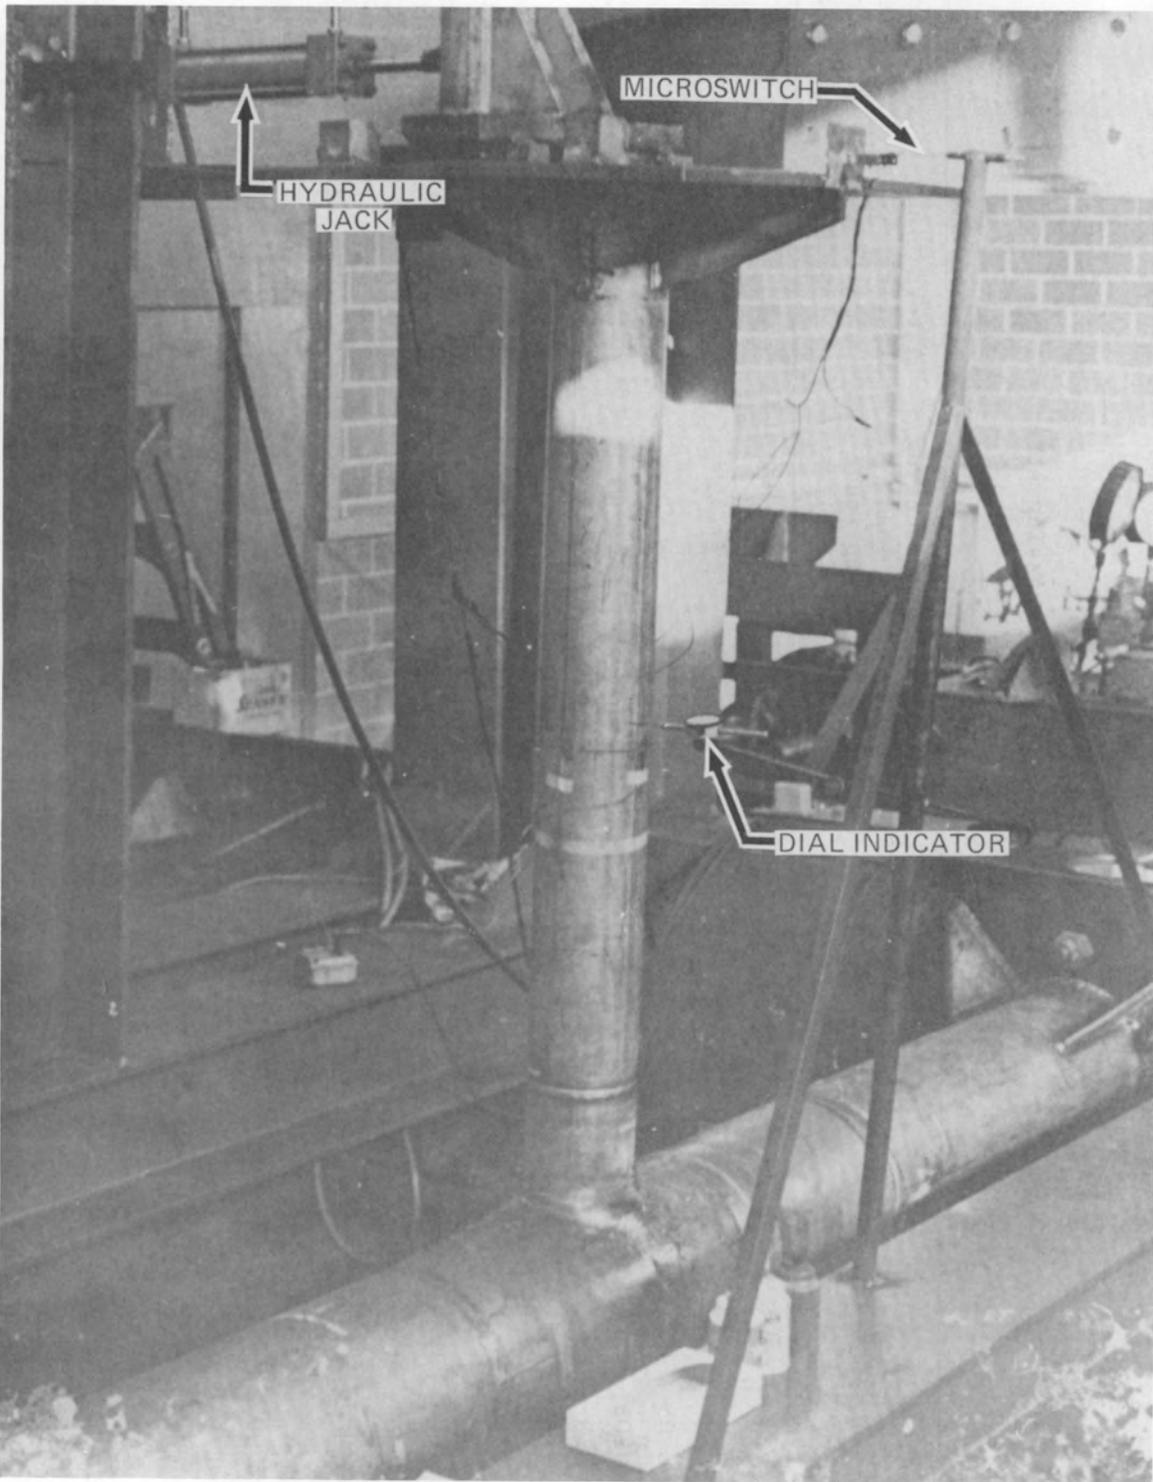

Fig. 2.13. T-8 in loading frame set up for $\pm F3Z$ fatigue test.

microswitch was then fixed so that the maximum displacement could not be exceeded in that direction on subsequent cycles. The procedure was then repeated for the second microswitch.

As may be seen from the values given in Table 2.5, this experimental procedure resulted in alternating equivalent elastic principal stress amplitudes that were very nearly equal to the intended value of 83,400 psi. One of the microswitches, the dial indicator, and the hydraulic jack may be seen in Fig. 2.13, which is a photograph of T-8 during the fatigue test. The total strain ranges after a shakedown of ten cycles are shown in Table 2.6. After ten cycles, no additional strain readings were taken.

Table 2.6. Strain ranges
after shakedown^a

Model	Gage	Strain range (μ in./in.)
T-4	67-05	8,750 ^b

	90-06	4,560

^aMeasured after ten cycles on leg 2 of the strain rosette.

^bThe initial strain range for T-4 was 14,350 μ in./in. Initial strain ranges were not recorded for the other tees.

3. DISCUSSION OF ELASTIC-RESPONSE TEST RESULTS

In addition to the initial examinations conducted at the test site, the strain-gage data were screened by two processes prior to final acceptance. The first was a computerized check based on the assumption of linear elastic response. The second was more subjective, involving visual comparisons and the judgment of an analyst. After the data analysis was complete, normalized principal stresses and stress intensities (according to the Code definition) were computed, tabulated, and plotted in three different graphical forms for further analysis. Complete sets of these data are given in Appendixes VI, VII, and VIII. A summary of the maximum values is given in this chapter.

3.1 Reduction of Strain-Gage Data

As part of the experimental stress analysis, a concurrent reduction of data was performed using the computer program LINDA and subroutine NOSEY. This initial reduction was done to monitor the data acquisition process so that faulty strain gages could be identified and corrected if possible. The data were re-reduced later, using an updated version of NOSEY. The diagnostic procedure implemented by NOSEY is summarized in Sect. 3.1.1. A detailed description of the program appears in Ref. 10. The output from the NOSEY runs were plotted on graphs of stress vs strain-gage location. These plots were then checked for anomalous data points and adjusted if necessary. This final adjustment is discussed in detail in Sect. 3.1.2.

3.1.1 Evaluation of strain-gage data

The computer code NOSEY implements a diagnostic procedure for identifying and separating errors in strain measurement and load application. The procedure depends on the hypothesis that the strains obtained from the tests are proportional to the loads. In this analysis, the data are subjected to three separate tests: the linearity test, the variability test, and the load-adjustment test.

In the linearity test, the nine data points acquired for each gage under each loading condition are fitted to a straight line by the method of least squares. The program identifies and eliminates data that deviate excessively from linear behavior, leaving only data lying within a specified tolerance band. Because the procedure depends only on the assumption of linear behavior, any nonlinearity identified in this test must be due to either an error in the strain data acquisition or to the recorded value of the applied loads.

The width of the tolerance band is dictated by the accuracy required, but it is also limited by the resolution of the strain data acquisition system. For these tests, the larger of two values — 8 $\mu\text{in./in.}$ or 15% of the maximum strain at a given gage — was used as the tolerance limit. Any gage for which more than 30% of the data was lost was flagged in the computer output with an asterisk, and a double asterisk was used to indicate complete failure of the gage.

The variability test compares the response of all the strain gages in the structure. This is done by normalizing the data from each gage to the maximum load and strain recorded for that gage. After normalizing, all the data for a given loading vary between a minimum of 0 and a maximum of 1.0. In the ideal case, the normalized data points will all lie on the line passing through the origin and the point (1, 1). If there is a large amount of scatter in the data for a given load case but the mean values of the data lie on the ideal response line, then the variations are due to inaccuracies in the strain data acquisition (i.e., strain gages, wiring, and/or data acquisition system). If, however, there is little variation in the values of the normalized strain, but the mean for a given load case is not on the ideal response line, then an error in the recorded loading is indicated.

The load-adjustment test selects the most consistent set of normalized strains and uses these data to mathematically adjust the value of the applied loads. If the adjustments are large, all three of the tests are performed again using the new estimates for the loads.

Computer program LINDA,¹⁰ which uses NOSEY as a subroutine, was used to reduce the strain data to calculated stresses in both local and

principal coordinates. A complete tabulation of these data is presented in Appendix VI. There is a separate table for each load condition on each model. Each table presents measured strains, maximum and minimum principal surface stresses, shear stresses, stresses along and normal to the ϕ lines, and the angle in the counterclockwise direction from either the ϕ line or the crotch line (depending on the orientation of gage 2) to the maximum principal stress. The value of the load for which LINDA computes and prints the strains and stresses is controlled by the user. In the tabulations of Appendix VI, the indicated pressures and moments correspond to those loads that will give a maximum principal stress of 1000 psi using the nominal dimensions of the piping. The nominal force loads in the transverse directions are equal to the value that will produce a bending stress of 1000 psi for the nominal dimensions. Specifically, the nominal stresses are defined by the following relations for the different loadings:

$$\begin{aligned}
 \sigma_{\text{nom}} &= 1000 \text{ psi,} \\
 &= p D_o / 2I_r \text{ (internal pressure),} \\
 &= M D_o / 2I_r \text{ (moment on run),} \\
 &= M d_o / 2I_b \text{ (moment on branch),} \\
 &= FL_r D_o / 2I_r \text{ (transverse force on run),} \\
 &= FL_b d_o / 2I_b \text{ (transverse force on branch),} \\
 &= F/A_r \text{ (axial force on run),} \\
 &= F/A_b \text{ (axial force on branch).}
 \end{aligned}$$

The nominal values for the geometric parameters D_o , d_o , T_r , T_b , I_r , I_b , L_r , L_b , A_r , and A_b were given earlier in Tables 2.2 and 2.3. For the full-outlet tees T-4, T-6, and T-7, the branch pipe and the run pipes have the same nominal dimensions, and thus the values for the nominal stresses are independent of whether the moment loadings were applied on the branch or run. However, for the reducing-outlet tees T-8 and T-15, the nominal dimensions of the branch and run are different. For these, the nominal stresses were calculated using the dimensional properties of the pipe on which the loading was applied. For internal pressure, the

section properties of the run pipe were used for all the tees. An elastic modulus of $E = 30 \times 10^6$ psi and Poisson's ratio of $\nu = 0.3$ were used in these calculations (i.e., those given in Appendix VI).

Note that if a moment couple is applied in bending and then in torsion to a circular beam, classical beam theory predicts that the maximum normal stress in the bending case will be twice the maximum shear stress in the torsion case. However, for ASME Code-related work, this study is concerned with stress intensity, which is defined as the absolute value of the largest principal stress difference or twice the maximum shear stress at a point. Therefore, a given couple will produce the same stress intensity regardless of whether it is applied in bending or in torsion.

There are two advantages to this normalizing scheme. First, it provides an easy means for comparing the stress intensification effect of different loads on the same tee and identical loads on different tees. Second, by scanning the tabulations for maxima, one can obtain specialized stress indices, and comparing these values would be a first step toward the development of generalized indices for use in design codes and standards.

3.1.2 Final screening and reduction

The data reduction performed by NOSEY is geared to establishing a constant strain-to-load ratio for each gage and hence for each rosette. If some of the data obtained from any one of the gages do not pass all the tests of NOSEY, the confidence in the value of the ratio for that gage is diminished. Therefore, the data were subjected to a final screening in which the response of each rosette whose data had been partially rejected by the linearity test was compared by the analyst with the responses of adjacent rosettes. This was done by studying computer graphs of the maximum and minimum principal stresses plotted as a function of gage location. If an excessively steep stress gradient occurred at a gage whose data had been partially rejected, the plot was compared with other cases for which similar stress solutions could be expected.

The questionable data points were then adjusted as necessary. These comparisons were based on certain similarities in loading and on symmetries in the test setup that could be exploited in predicting trends of the stress plots for identification of questionable data points. These comparison tests are discussed more fully in the following paragraphs.

In this test series, the transverse forces were applied near the ends of the branch and the run pipe at distances ranging from 76.1875 to 78.375 in. from the center of the tee (Table 2.3). If one conservatively assumes that the maximum nominal shear stress is equal to twice the applied shear force divided by the cross-sectional area, then the ratio of the maximum bending stress to the maximum shear stress will range from about 13.0 on the T-8 and T-15 run pipes to about 25.4 on the branches for the same models. The factor of 2 comes from thin-shell theory and represents the highest shear stress solution for a beam with a circular cross section. Also, if the usual assumptions of beam theory are imposed, the value of the shear stress will be zero at the point of maximum bending stress. Therefore, the stress solutions due to F2Y and -M2Z should be very similar, and the maximum principal stress in each case will be due entirely to bending. The same holds for F2Z and M2Y, F3X and -M3Z, and F3Z and M3X.

The models are essentially symmetric about the plane formed by the intersection of the axes of the run and the branch (the longitudinal plane). There is also geometric symmetry about the plane perpendicular to the run and containing the branch axis (the transverse plane). Because the 0° end of the run was fixed while the 180° end was free, the boundary conditions are not symmetric about this plane. However, these ends are sufficiently removed from the tee that the constraint effects can be expected to be negligible in the region of the tee. Therefore, the elastic response of each model to internal pressure and to loads applied at the free end of the run should be similar for the two opposing quadrants on which the strain gages are placed. Loadings on the branch, however, cannot be expected to give similar responses in the opposing quadrants because there was no reaction force at the free end, and the symmetry conditions thus break down.

Because the nominal dimensions of T-4 and T-6 are the same and those of T-8 and T-15 are also the same (Table 2.2), similar elastic responses should be anticipated for each pair. This expected similarity was the third and final basis for comparison. It was not used extensively, however, because differences in stress plots were in some cases due to real differences in the shape of the tees, resulting from different manufacturing techniques rather than from irregularities in the testing equipment or procedure.

The results of the final strain-gage data screening are shown in Appendix VII, Table VII.1. A total of 143 stress values were adjusted, or about 1% of the 14,365 solutions that were obtained. Of the stresses that were adjusted, 116 (81%) were for the inside surface, reflecting the greater difficulty of installing strain gages on the inside of the tee. At the time that the adjustments were made, however, no graphs were available for the M3X loading on T-6, and these values were adjusted by scanning the tabulated values in the computer output. The -M3Y loading on T-4 had so many questionable data points that no basis could be found for making adjustments, and the curves were simply left alone.

Special mention is required for two of the adjusted strain-gage results — for the internal pressure loading on T-7 and for the out-of-plane bending on the branch (-M3X) of T-4. They are the only two cases in which the *maximum* values anywhere on the tee were adjusted. The values shown in Table 3.1 were abstracted from Table VII.1 of Appendix VII.

For T-7 under internal pressure, the test data (NOSEY) indicated that the largest maximum principal stress (35.33 psi/psi pressure) occurred on the inside surface in the longitudinal plane near the crotch line — at strain rosette 0-17. Although the possibility that the data were good was not ruled out,* both the maximum and minimum principal

*Several possible reasons for the anomalous behavior were postulated, such as the possibility of a surface flaw in the tee or an air bubble under the gage; however, because this particular gage gave consistent results for the other loadings and because the gage was on the inside surface where it could not be examined until after the fatigue test was completed, it cannot be positively determined that the data were inaccurate.

Table 3.1. Adjustments in maximum stress values for T-4 and T-7

Tee	Load	Rosette No.	Normalized ^a principal stresses (ksi)			
			NOSEY		Adjusted values	
			Maximum	Minimum	Maximum	Minimum
T-7	P	0-17	35.33	8.39	17.0	4.0
		0-16	24.63	-4.81	20.5	3.5
T-4	(-M3X)	67-5	0.485	0.087	0.44	0.14

^aFor this comparison, the stresses are normalized to the loads, $P_{nom} = 1000$ psi and $M3X_{nom} = 1000$ ft-lb.

stresses were adjusted after comparing them with data from the opposite quadrant ($180^\circ \phi$ line). The maximum normalized stress intensity on the $180^\circ \phi$ line was 18.10. Further justification for the adjustments is based on a comparison with data from the photoelastic model studies of T-7 under internal pressure (see Ref. 15). The photoelastic studies indicated that the maximum stresses occurred at the same locations (i.e., in the longitudinal plane) but had a maximum normalized value of 14.0. Thus, both the data from the opposite quadrant of the steel model and the data from the photoelastic model indicate that the adjusted maximum value for T-7 (i.e., 20.5) is reasonable and conservative.

The relatively small adjustments in the principal stress values shown for the -M3X loading on T-4 were based on a comparison with results from the F3Z (out-of-plane transverse force) loading. These adjustments were considered necessary because of the erratic behavior of gage 2 in rosette 67-5.

3.2 Presentation and Discussion of Strain-Gage Data

The strain-gage data are presented in Appendixes VI-VIII for two different stages of reduction. The values tabulated in Appendix VI, which are from the LINDA output, were all calculated using a modulus of

elasticity of $E = 30 \times 10^6$ and Poisson's ratio of $\nu = 0.3$. Note also that the data have not been screened by the procedure described in Sect. 3.1.2. Appendixes VII and VIII contain computer plots and tabulations of the data after the final adjustments were made. All the data in these appendixes are normalized to 1000-psi nominal stress, as discussed in Sect. 3.1.1.

During the course of this test series, the data reduction subroutine NOSEY was updated several times, and the data presented in Appendixes VI--VIII represent the output from several different revisions. Therefore, there are some minor inconsistencies in the data that are primarily caused by small variations in the diagnostic parameters used in NOSEY at different stages in the development of the program.

The data given in Appendixes VII and VIII have been checked and adjusted. The presentation includes a summary of the adjustments, tabulations of stress intensities, contour plots of stress intensities, plots of stress intensity vs projected gage line distance, and maximum stress intensity vs angular displacement of the gage line. The adjusted data points have been flagged in both the tabulations and the plots, with the exception of the contour plots. Because Appendixes I--IX are on microfiche and thus may be somewhat less accessible than full-size printed material, a representative sampling of the data from Appendixes VII and VIII has been abstracted for full-size presentation in Sect. 3.3. For the pressure-loading case, this study has included tabulations of the normalized stresses and strains, and gage-line, circumferential-line, and contour plots of the normalized stress intensity for the quadrant of the tee in which the maximum value occurred.

In general, the data given in the appendixes show clearly that the stress distributions over the body of the tees for *all* the loadings were smooth, that is, without steep gradients or sharp discontinuities. In addition, the gage-line plots (Appendix VIII.2) show that the maximum values always occurred either at or very near strain-gage locations. This reinforces the conclusion from the brittle lacquer tests that the strain-gage coverage was adequate for every model.

A quick scan of the stress-intensity tabulations of Appendix VIII shows that for internal pressure (see full-size representative samples

in Sect. 3.3), the maximum stress for all five tees occurred on the inside surface near, but not necessarily in, the longitudinal plane. For bending-moment and transverse-force loadings on the branch, the maximum stresses occurred on the outside surface at various angular locations around the branch. Such generalizations, however, cannot be made for the other loading cases.

The highest normalized maximum stress intensities resulted from axial loads on the branch. Although nuclear piping systems are designed so that tees should not be subjected to large axial loads, the relatively high stresses measured in these experiments suggest that axial loads, as well as pressure and moment loads, should be considered in design.

Table 3.2 gives a summary of the locations (by gage number) and magnitudes of the maximum stress intensities for each of the 13 loadings on each of the 5 tees. The table is arranged so that results from the bending-moment and corresponding transverse-force loadings (e.g., M3Z and F3X) can be easily compared, and the maximum stresses for each pair can be verified as approximately equal for all five tees. The largest difference between stress intensities in such a pair was for the in-plane bending applied to the run of T-7. In this case, the two maximum stress intensities differed by about 35% and did not occur at the same location. Of the remaining 19 pairs of bending and shearing loads, all gave maximum stresses within 15% of each other, and 16 gave maximum stresses within 10% of each other.

The above differences are due to at least three factors. First, even though the effect of shear is small, it is not negligible and an influence of a few percent may be expected. Second, the nominal bending stress for the applied transverse force was calculated using a moment arm equal in length to the distance from the intersection of the pipe and run axes to the point of load application. This will introduce some errors, since the maximum bending will not always occur at this point. Third, errors may be caused by faulty data that survived all the screening procedures.

Because the maximum stress intensities given in Table 3.2 are normalized in the same fashion as the stress indices given in Table NB-3681(a)-1

^dSI = maximum normalized stress intensity. See Sect. 3.1.1 for the normalizing convention.

of the ASME Code,* a direct comparison of the two can be made. It must be emphasized, however, that the Code indices are intended to represent maximum stress intensities resulting from any admissible combination of loadings. Thus, firm conclusions regarding the adequacy of the Code indices cannot be made until the experimental data are studied in the proper context. A separate report on that subject is being prepared.

*Normalization is the same except for use of the nominal section modulus rather than the approximate modulus used by the Code.

3.3 Representative Data for Pressure Loads

For those readers who may not have ready access to a microfiche reader or who may not be interested in all the strain-gage data given in the appendixes, a portion of the data for the internal pressure loading case has been abstracted for full-size presentation and further discussion. Figures 3.1 and 3.2 are computer-generated contour plots of normalized stress intensities for the inside and outside surfaces of T-4. Figure 3.1 shows the 0° to 90° quadrant, whereas Fig. 3.2 shows the 180° to 270° quadrant. As may be seen, the maximum values occurred on the inside surface on the longitudinal plane. The stress patterns, however, are not entirely symmetrical because somewhat higher stresses occurred in the 0° to 90° quadrant than in the 180° to 270° quadrant. Similar contour plots for the other tees and for the other loading conditions are given in Appendix VIII.

Figure 3.3 is a schematic illustration of the technique used to develop the gage-line plots shown in Fig. 3.4 for T-6 and T-7 for internal pressure. Complete sets of gage-line plots are also given in Appendix VIII. These figures show the normalized stress intensities for the gage line (i.e., same ϕ angle) in which the *maximum* value was located, as a function of projected distance. As shown in Fig. 3.4, the maximum value for both T-6 and T-7 was on the run side of the crotch. The maximum values for T-15 was also on the run side, whereas for T-4 it was on the branch side and for T-8 it was located on the crotch.

Figure 3.5 shows the maximum stress index values from each ϕ line of T-4 plotted as a function of the diametral plane angle ϕ . For all of the tees except T-6, the absolute maximum was located in the longitudinal plane ($\phi = 0^\circ, 180^\circ$) on the inside surface. For T-6, it was displaced about 20° to the side.

Numerical values for the stress intensity measured at each gage site in each of the two quadrants for both inside and outside surfaces are listed in Tables 3.3–3.7. The data in the tables are arranged in four sets, one set for each quadrant surface, and the maximum value in each set is circled. The largest of these, along with the identifying gage number, was given earlier in Table 3.2. A few of the values given

in Tables 3.3–3.7 have been adjusted, as discussed in Sect. 3.1, and are identified by a solid triangle (\blacktriangle). Values for the stress intensities for all the gage sites, together with the XYZ coordinate location data given in Appendix III, should provide valuable sets of experimental benchmark data for comparison with analytical solutions and/or photo-elastic model studies.

There are interesting aspects of the contour plots and the ϕ -line and circumferential-line plots that cannot be easily seen by looking at the tabulated data. For example, the contour plots show that the elastic response for all five tees was essentially symmetric about the transverse (90° , 270°) plane for internal-pressure loading. The behavior of T-6 and T-8 was more symmetric than that of T-4, T-7, or T-15, which, in general, reflects a more uniformly symmetric geometry. None of the models, however, were perfectly symmetric, as was evidenced by the fact that the *maximum* stress values were not symmetric. The stress gradients were reasonably smooth for all the tees, and there is a notable lack of stress discontinuities or isolated regions of extremely high stresses, which tends to confirm the advantage of having a contoured outer surface that is free of geometric discontinuities.

When one compares the behavior of T-4 with T-6 and T-8 with T-15, which were nominally the same size and material but made by different manufacturers, somewhat different response characteristics are apparent from the contour and line plots. These figures (see Appendix VIII) show that the maximum stresses from internal pressure for T-4 and T-15, made by manufacturer I, were located in the longitudinal (0° , 180°) plane as one would intuitively expect, whereas the location of the maximum stresses for T-6 and T-8, made by manufacturers III and II, respectively, were located to the side of the longitudinal plane. For tees T-6 and T-8, the largest stress intensities in the longitudinal plane were substantially less than the maximum values. Nevertheless, both T-4 and T-15 had higher maximum stress indices for internal pressure than did T-6 and T-8 — 4.417 vs 3.310 and 3.654 vs 2.700, respectively.

These maximum stress differences can be attributed to differences in geometrical details, because all the tees conformed to the same overall dimensional requirements of ANSI B16.9. A visual examination of the tees showed that T-4 had generally thicker walls than T-6 (T-4 weighed 21 lb more than T-6); it also had more reinforcement material on the inside in the longitudinal plane at the crotch and a shorter transition radius on the outside surface. The external surface transition for T-4 was essentially a circular fillet with a radius of about 1.1 in., whereas the transition region for T-6 extended essentially from the branch outlet

to the run outlet (i.e., from weld prep to weld prep) in the longitudinal plane and had a variable radius that ranged from a minimum of ~2.3 to ~3.0 in.

The two stainless steel tees T-8 and T-15 were more nearly alike than the carbon steel tees T-4 and T-6. They weighed more nearly the same (155 and 143.5 lb, respectively) and had very little excess reinforcing material on the inside of the crotch. The transition radius was somewhat larger for T-8 than for T-15 (about 0.75 and 0.65 in., respectively), and the overall shape of T-8 was more symmetrical and streamlined than that of T-15. The diameter of T-15 appeared to have been made "oversize" and then reduced at the welding ends to meet the B16.9 standard dimensional requirements.

These limited comparisons tend to support the conclusion that the radius of the transition has a more important influence on the maximum stress intensity than does the overall wall thickness or the amount of reinforcing material on the inside corner of the crotch. This conclusion is consistent with results from theoretical studies by Rodabaugh and Gwaltney¹⁶ and by Gwaltney and Corum¹⁷ on the effects of reinforcement design for nozzles in spherical pressure vessel heads. Their studies showed that reinforcement material placed entirely on the inside surface has essentially no influence in reducing the maximum stresses and that, to be most effective, at least half of the reinforcement should be on the outside surface.

The comparisons also seem to indicate that overall shape and model symmetry contribute to the magnitude of the maximum stress intensity. The summary of maximum normalized stress intensities in Table 3.2 tends to support these conclusions for most of the force and moment loadings as well as for internal pressure. The exceptions are for T-8 and T-15 force and moment loadings on the run where the maximum values are slightly higher for T-8 than for T-15.

4. DISCUSSION OF FATIGUE TEST RESULTS

As stated in Sect. 2.3, fatigue failure for each of the tees was expected in about 7000 cycles of moment loading on the branch, with failure being defined as a leak. For the fatigue test of T-4, which was the first to be tested, the first dye-penetrant inspection was made after 1500 cycles. It was felt that this would be early enough to detect crack initiation. However, a number of surface cracks had already appeared in the vicinity of gage 67-05 and at a symmetrical location at about $\phi = 239^\circ$. Apparently, these cracks were initiated several hundred cycles before the first inspection. For this reason, the inspections were performed every 500 cycles on subsequent tests.

At the end of each test, the pipe extensions were cut off, and the inside surfaces were inspected using liquid dye penetrant, after which the tees were returned to ORNL.

Fatigue test results for each of the tees are discussed individually in the following paragraphs. In Sect. 4.2, an attempt is made to evaluate all the data and draw some general conclusions.

4.1 Fatigue Crack Initiation and Failure

The dye-penetrant tests showed that for every model except T-6, crack initiation and eventual failure occurred as expected in the vicinity of the most highly stressed region. For T-6, which failed sooner than any of the other tees, the location and orientation of the failure appeared to be somewhat anomalous. Cracks also appeared on the outside surface of every tee at various locations other than the failure point prior to eventual failure. No cracks were found on the inside surfaces of T-7, T-8, and T-15 other than the failure cracks, whereas T-4 experienced some inside surface crack initiation.

In Subsections 4.1.1 to 4.1.5, the results from each test are discussed individually.

4.1.1 Results for T-4

Photographs of the fatigue cracks were taken at various cycle intervals until failure occurred after 2062 cycles. The crack that first appeared at $\phi = 67^\circ$ propagated along the crotch line until a leak ultimately occurred at $\phi = 90^\circ$, as shown in Figs. 4.1–4.5. The internal pressure in the tee was 1925 psig at the time of failure, and a high-pressure stream of water was expected. However, due to the size of the failure crack, the flow of water was similar to the flow from a faucet under low pressure.

After the tee had failed, the pipe extensions were cut off and the inside surface was inspected with a dye penetrant. Additional fatigue cracks were found on the inside surface at $\phi = 45^\circ$ and $\phi = 315^\circ$ lying in directions normal to the fatigue cracks on the outside surface. These cracks may be seen in Fig. 4.6 along with the fatigue crack that propagated from the outside surface and eventually resulted in the leak. (The cracks were filled with a white lacquer to make them stand out in the photograph.) The principal stress in the vicinity of these cracks was 2.09 ksi/1000 lb_f as compared with 2.77 ksi/1000 lb_f at gage site 67-05.

4.1.2 Results for T-6

The area within 22° on either side of the $56^\circ \phi$ line was given a dye-penetrant inspection every 500 cycles to detect crack initiation. No cracks were found during dye-penetrant inspections at the 500- and 1000-cycle intervals; however, after 1309 cycles, a considerable amount of water was noted on the floor near T-6. Investigation revealed the existence of a large crack about 1 ft long between the 90° and $22^\circ \phi$ lines, as shown in Fig. 4.7. Internal pressure was lost, and most of the water in the tee had drained out. The facility was shut down, and a complete inspection of the outside surface was made.

The only other cracks on the outside surface were a series of small cracks between the 270° and $0^\circ \phi$ lines running parallel to the direction of principal stress, perpendicular to the expected directions. On the inside surface, fatigue cracks, shown in Figs. 4.8 and 4.9, were located

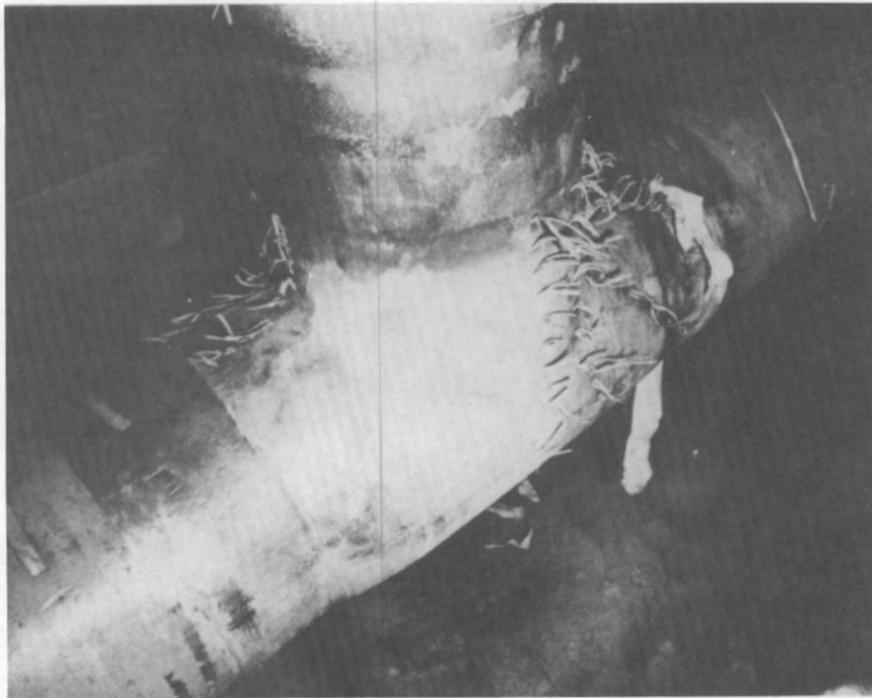

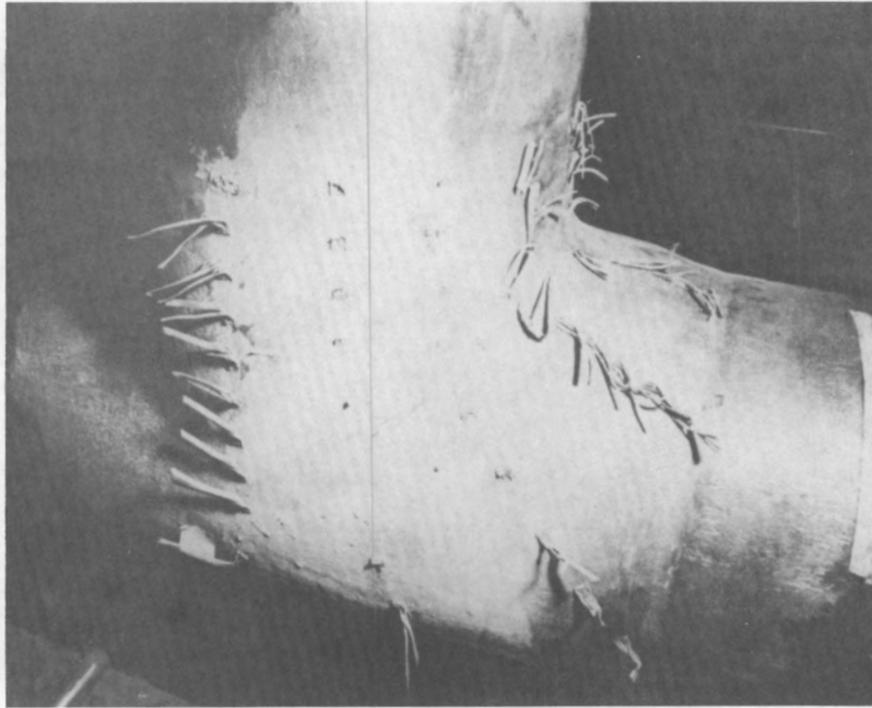

Fig. 4.1. Fatigue cracks in T-4 after 1651 cycles.

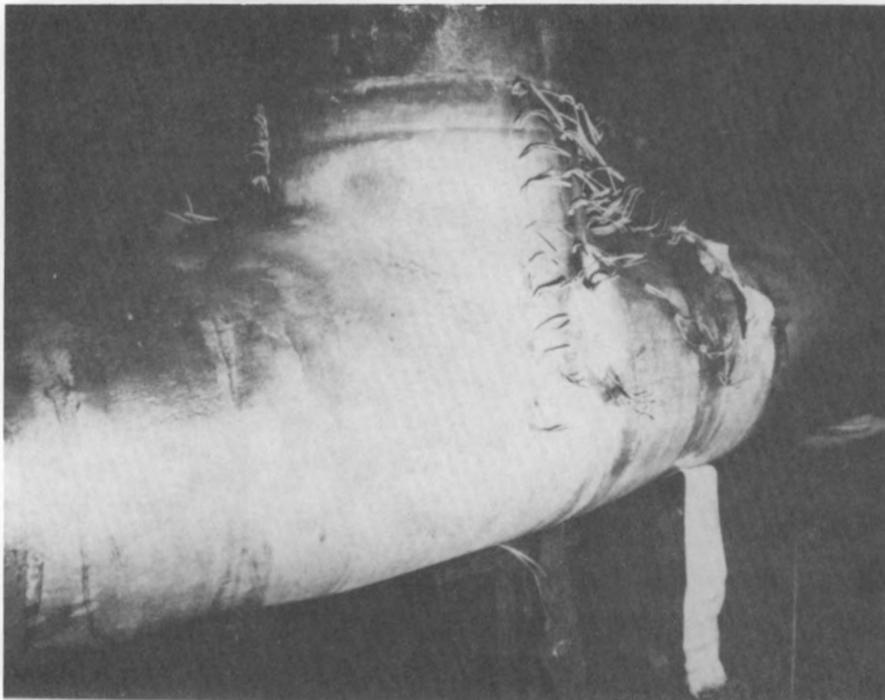

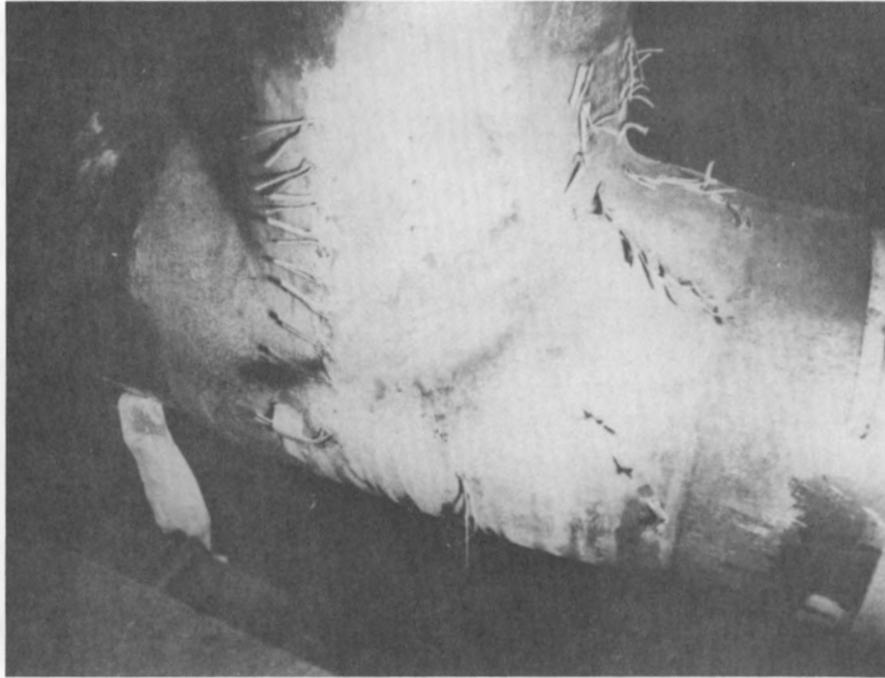

Fig. 4.2. Fatigue cracks in T-4 after 1760 cycles.

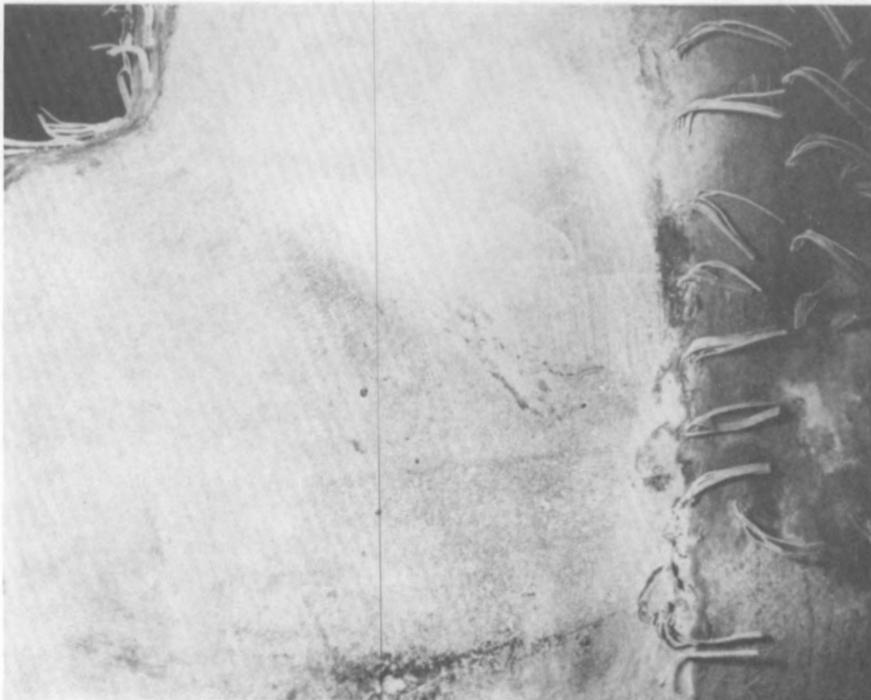

Fig. 4.3. Fatigue cracks in T-4 after 1970 cycles.

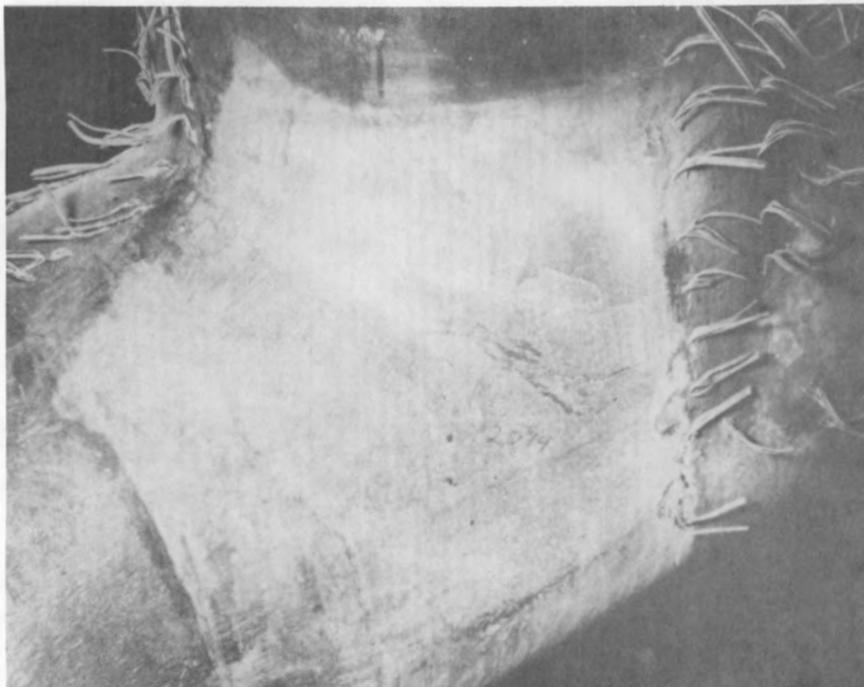

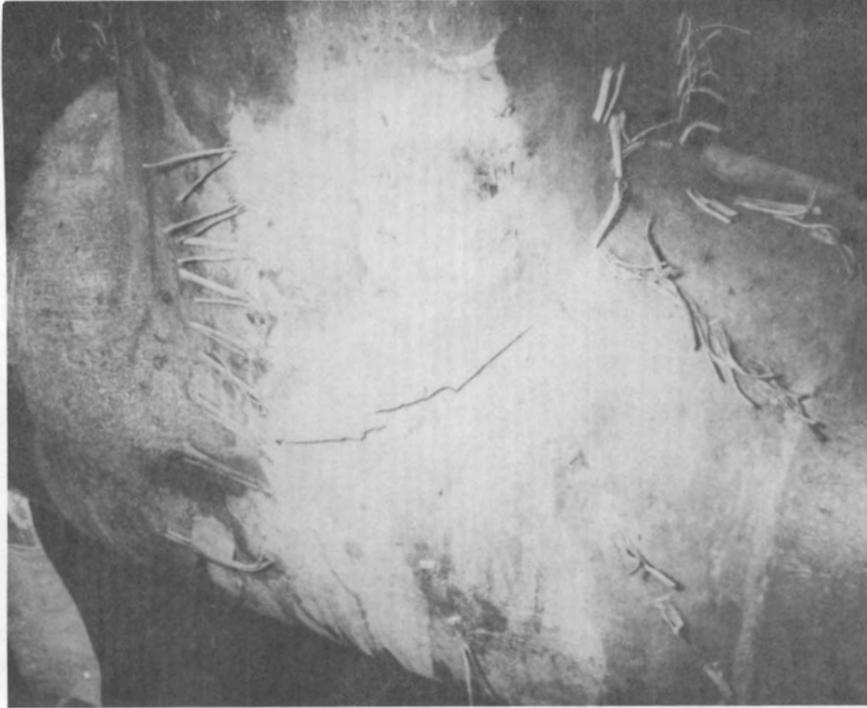

Fig. 4.4. Fatigue cracks in T-4 after 2019 cycles.

Fig. 4.5. Fatigue cracks in T-4 after failure at 2062 cycles.

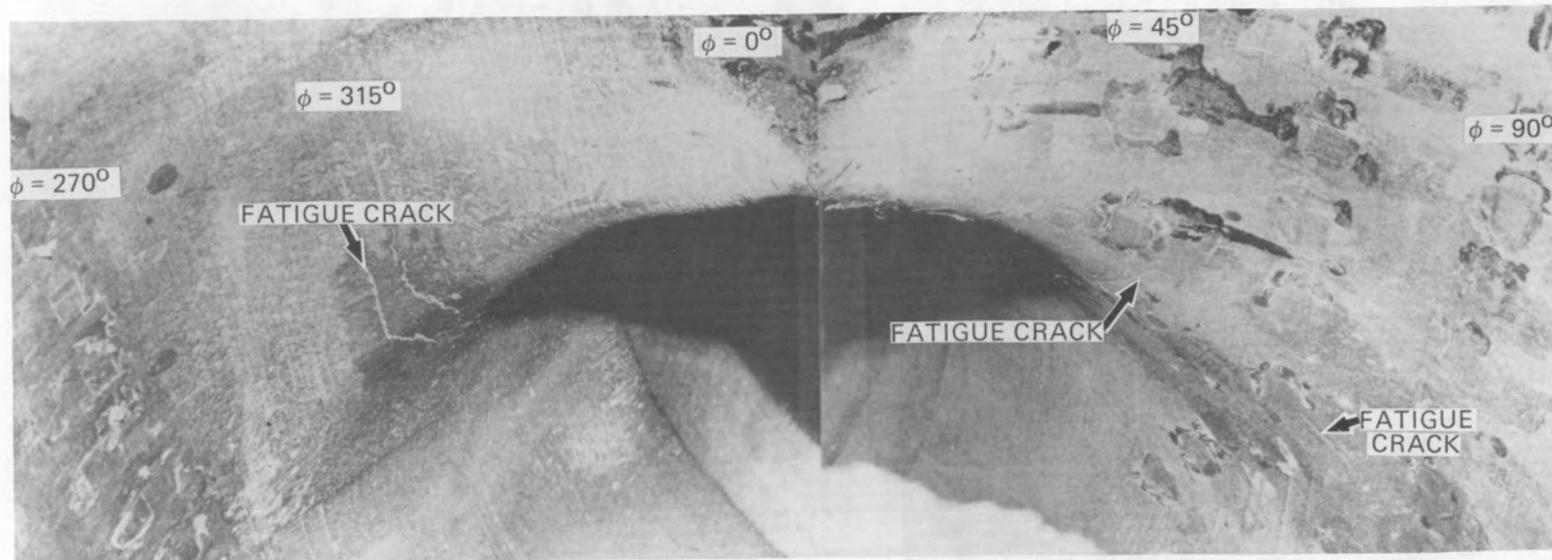

Fig. 4.6. View of inside surface of T-4 after fatigue testing.

M&C PHOTO Y114162

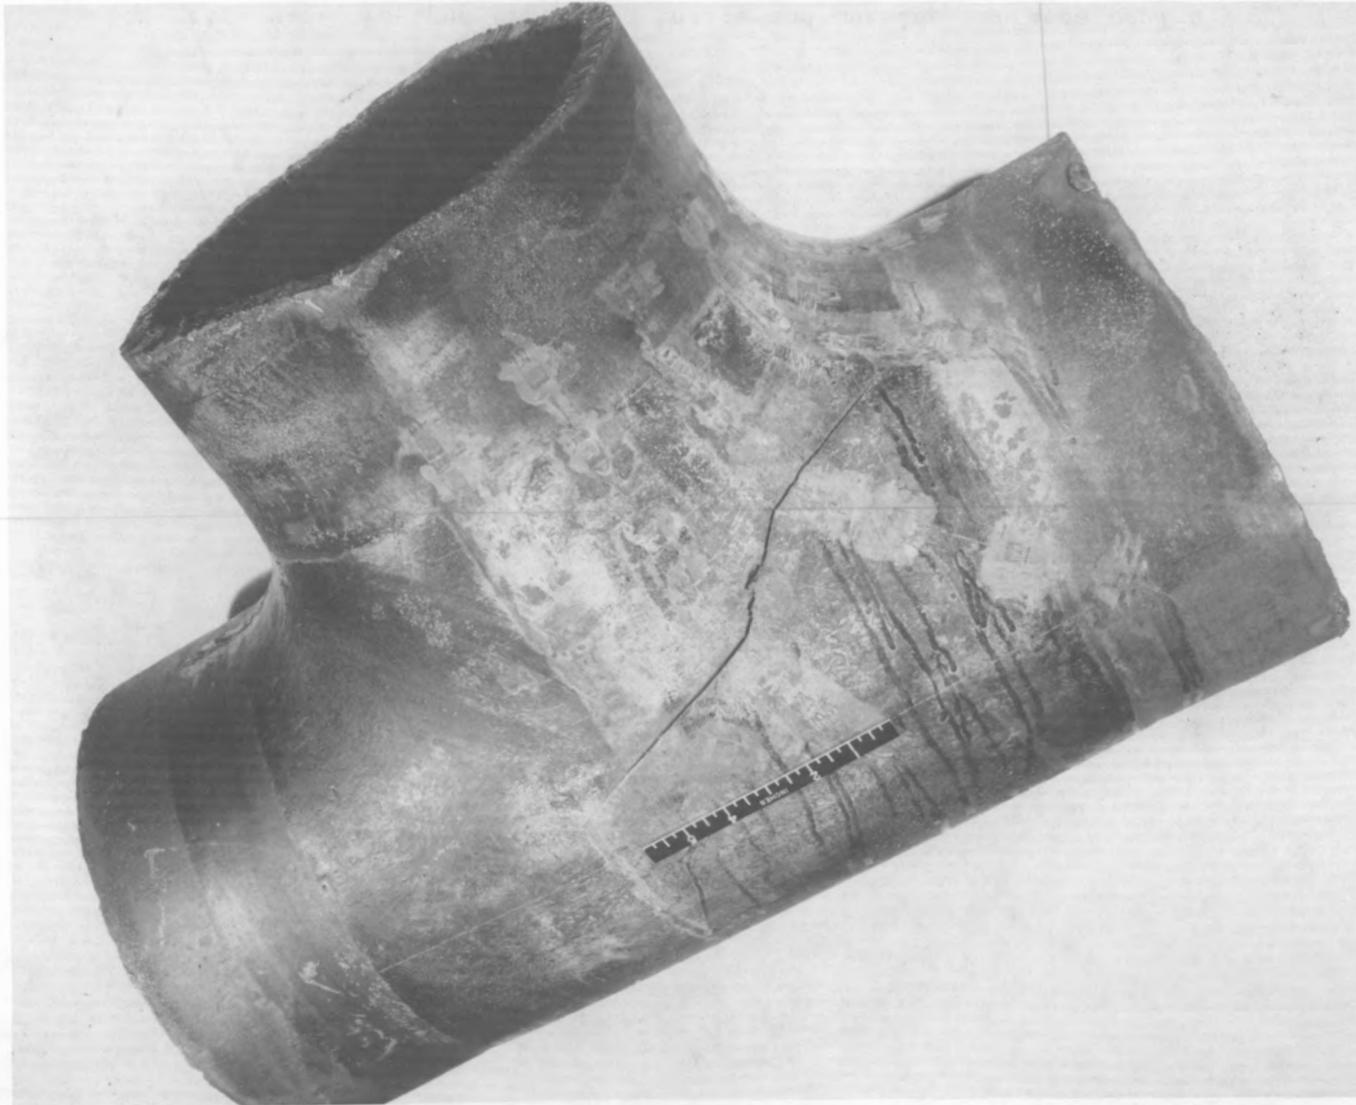

Fig. 4.7. Fatigue crack in T-6 after failure at 1309 cycles (from $\phi = 90^\circ$ to $\phi = 22^\circ$).

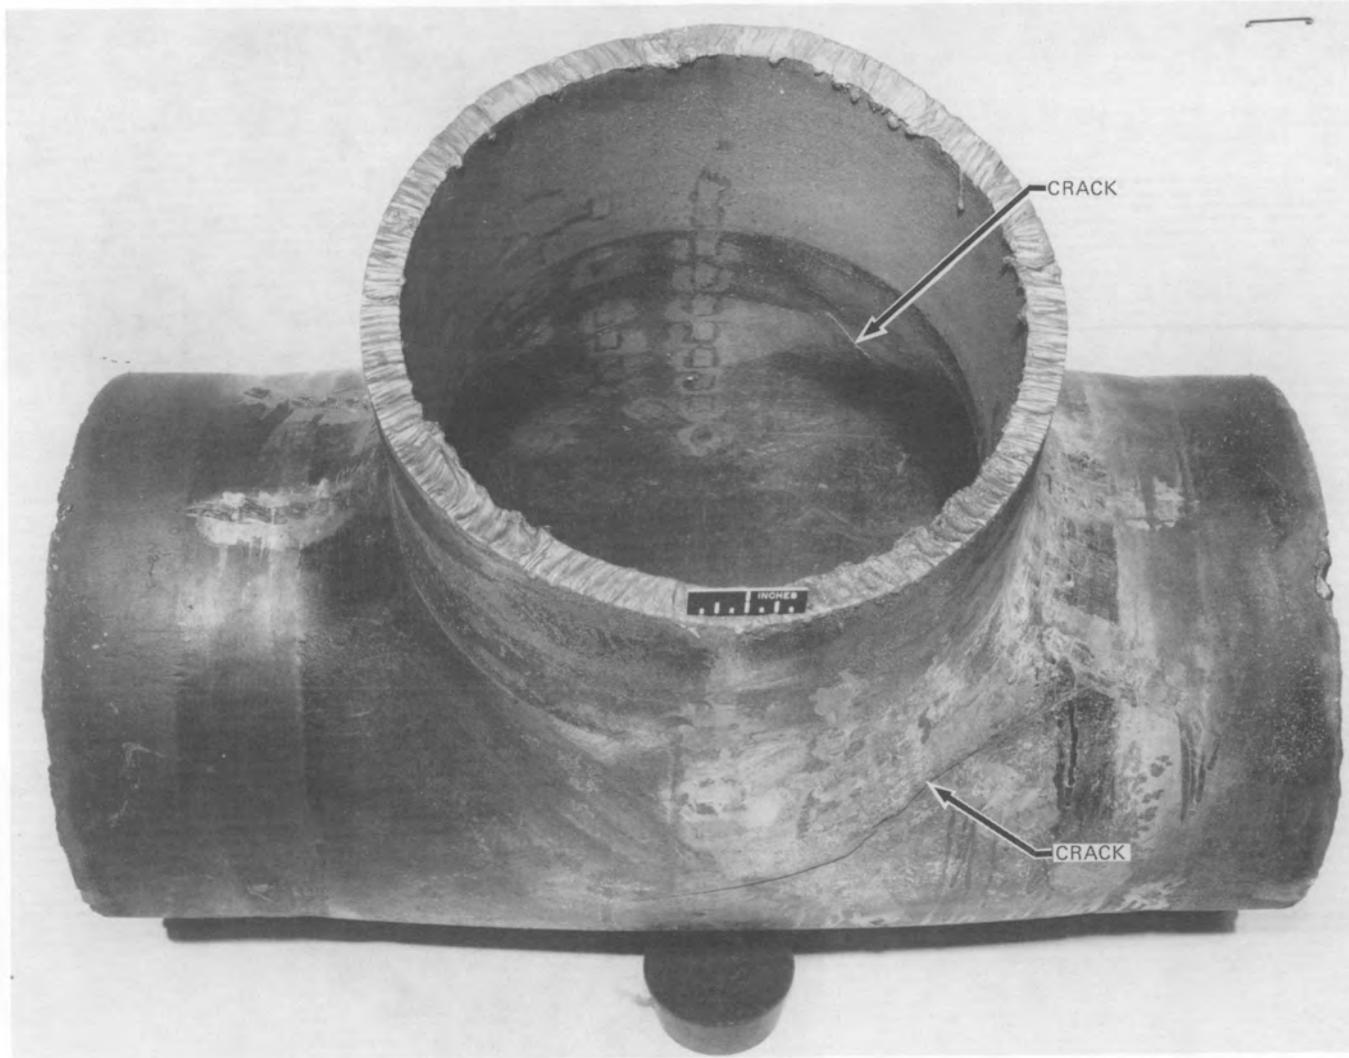

Fig. 4.8. Fatigue cracks on inside and outside surfaces of T-6 after failure.

Fig. 4.9. Fatigue cracks on inside surface of T-6 after failure at 1309 cycles ($\phi = 335^\circ$).

at about $\phi = 335^\circ$. Although these cracks had not propagated through the wall, they were of sufficient length and orientation to indicate the potential for eventual failure had the tee not already failed.

After T-6 was returned to ORNL, a rather extensive posttest examination was conducted. The cracked areas were removed from the tee with a cutting torch, and the failure crack surfaces were exposed. Figure 4.10 shows an elliptically shaped crack that apparently initiated at the outside surface of the tee and propagated inward at a rapid rate causing instantaneous structural failure. The chevron pattern on the fracture surface and the absence of any striation morphology supports the conclusion of fast fracture. An extensive visual examination of the fracture surface indicated that failure could have propagated from small surface cracks that were about 0.3 in. deep and perhaps 0.6 in. long, although such surface flaws were not in evidence when the tee was purchased.

Room temperature tensile and Charpy-V notch (C_v) properties of the steel, obtained from samples taken from the bottom of T-6, are summarized in Table 4.1. Although the Charpy energy is somewhat low, there is nothing unusual in the data to suggest that the material was not fully acceptable for ASME Class 1 construction.

Table 4.1. Room-temperature mechanical properties of T-6

	Tensile yield strength (ksi)	Ultimate tensile strength (ksi)	Tensile elongation (% in 2 in.)	Area reduction (%)	Charpy energy (ft-lb)
Minimum	40.7	65.3	34	59.1	42
Average	43.1	71.0	36	63.9	71
Maximum	46.1	72.8	38	68.1	122

4.1.3 Results for T-7

The area within 22° on either side of the $0^\circ \phi$ line was given a dye-penetrant inspection every 500 cycles to detect crack initiation.

M&C PHOTO Y116781

Fig. 4.10. Fracture surface of T-6 failure crack.

The first crack started near the 0-02 rosette in the root radius of the transition weld from the run pipe to the tee after 3528 cycles. Several small cracks then appeared in this root radius at about 10° on either side of the $0^\circ \phi$ line and propagated until one continuous crack was formed. These cracks did not grow to any significant depth and did not influence the final failure.

At 3843 cycles, a $3/8$ -in.-long crack was noted on the tee at the 0-07 gage site, and a $1-1/2$ -in.-long crack was noted at the 0-08 gage site. The crack close to the 0-08 rosette eventually propagated through the tee wall after 11,475 cycles. Before failure occurred, however, many small cracks had appeared in the area within 22° on either side of the $0^\circ \phi$ line, and two cracks were fairly deep at symmetrical locations at the 0-07 level at $\phi = 20^\circ$ and $\phi = 340^\circ$. The crack growth described may be seen in Figs. 4.11-4.15. Final inspection of the inside surface revealed no crack other than the one that propagated from the outside surface.

4.1.4 Results for T-8

The initial cracks were found during an inspection at 2035 cycles at the 78° and $90^\circ \phi$ lines just above the crotch line. Cracks were also found at symmetrical locations at the 270° and $282^\circ \phi$ positions after 3033 cycles. Figures 4.16-4.20 show the growth of the two sets of cracks from 3763 cycles to failure. The tee failed after 8979 cycles when leaks occurred at both 90° and 270° .

The pipe extensions were cut off, and the inside surface was inspected using liquid dye penetrant. No cracks were found other than the crack that propagated from the outside surface.

4.1.5 Results for T-15

The first cracks were found during an inspection at 3200 cycles at both the 90° and $270^\circ \phi$ lines. Figures 4.21-4.23 show the growth of the cracks from 7450 cycles to failure. The tee failed after 10,200 cycles when a leak occurred in the crotch region at 270° .

The pipe extensions were cut off, and the inside surface was inspected using liquid dye penetrant. No cracks were found other than the crack that propagated from the outside surface.

4.2 Evaluation of Fatigue Test Data

One of the major objectives of this test series was to obtain, under controlled laboratory conditions, piping component fatigue failure data that could be used, at least in a limited sense, to assess the adequacy of the fatigue design analysis procedures currently specified in the ASME Code for Class 1 piping systems. Because this procedure provides only a "lower-bound limit" on the cyclic life of the component under specified design conditions, no differentiation between crack initiation, crack growth, or structural failure is made. The loading conditions and the total number of loading cycles to structural failure are therefore the important variables for evaluating the Code analysis. These results are summarized in Table 4.2.

Table 4.2. Results from displacement-controlled fatigue tests of 12-in. NPS ANSI B16.9 tees

Tee No.	Constant internal pressure (psi)	Applied branch moment	Equivalent elastic alternating stress, S_a (psi)	Number of cycles to failure
T-4	1925	$M_o (\pm F3Z)$	$\pm 83,100$	2,062
T-6	1925	$M_o (\pm F3Z)$	$\pm 83,460$	1,309
T-7	3240	$M_i (\pm F3X)$	$\pm 85,358$	11,475
T-8	950	$M_o (\pm F3Z)$	$\pm 80,790$	8,979
T-15	950	$M_o (\pm F3Z)$	$\pm 84,640$	10,200

However, some additional information was obtained on crack initiation and shakedown strain range, which may be of value for further study. Crack initiation data are summarized in Table 4.3.

Table 4.3. Summary of crack initiation data

Tee No.	Cycles to crack initiation	Cycles to failure	Percent to initiation
T-4	<1,500	2,062	<72.8
T-6	>1,000	1,309	>76.3
T-7	<3,528	11,475	<30.8
T-8	<2,035	8,979	<22.6
T-15	<3,200	10,200	<31.4

It may be noted that for the three stainless steel tees (T-7, T-8, and T-15), crack initiation occurred at 20% to 30% of the total cycles to failure, whereas for the carbon steel tees (T-4 and T-6), crack initiation occurred in the neighborhood of 75% of the test life. In the case of T-4, the number of cycles to initiation is not known other than that it was <1500 cycles (73%). It appeared that crack initiation occurred several hundred cycles earlier, but this may not have been the case, because T-6 went from no detectable crack to failure within 300 cycles. Although crack initiation data from the carbon steel models is very limited and perhaps of doubtful significance, it appears that there is a significant difference in crack initiation behavior between the carbon and the stainless steel models. This is probably due to a difference in the crack-growth-rate characteristics of the two materials, because stainless steel is recognized as being less notch sensitive in fatigue than carbon steel. It does not seem likely that the difference is due to any major differences in the stress distributions in the respective tees, in the sense of "membrane" and "bending stresses," although redistribution of maximum stresses in localized regions may have been an important factor.

The strain range after shakedown (10 cycles) for each of the tees was also measured, but only at selected gage sites where the maximum stresses would occur, and then only for the No. 2 leg of the strain rosettes. These data, given earlier in Table 2.6, are summarized in Table 4.4.

Table 4.4. Maximum strain range after shakedown^a

Tee No.	Strain range ($\mu\text{in./in.}$)
T-4 ^b	8,750
T-6	11,500
T-7	4,980
T-8	7,996
T-15	5,680

^aMeasured after 10 cycles on leg 2 of the strain rosette.

^bInitial strain range for T-4 was 14,350 $\mu\text{in./in.}$

The only apparent observation that can be made from these data is that the shakedown strain range for the stainless steel models T-7, T-8, and T-15 tends to be lower than that for the carbon steel tees. Because each model was loaded to approximately the same maximum stress,* this seems to indicate that the stainless steel structures deformed plastically over a larger region than did the carbon steel models, thus redistributing the maximum stresses in a somewhat different and more favorable fashion. If so, both crack initiation and crack growth could be expected to take longer for the stainless steel tees because of the lower maximum stresses after the initial plastic deformations.

From these limited data, it seems apparent that further studies designed specifically to investigate crack initiation and growth, as well as the stress redistributions caused by high initial loadings, should be undertaken. One could then expect to develop improved correlations for the design of piping systems that are expected to operate in the "low-cycle" fatigue range, that is, 10^3 to 10^6 cycles to failure.

*Presumably, the maximum initial strains were also approximately equal. Unfortunately, the maximum initial strain was recorded only for T-4.

A comparison between the present fatigue qualification requirements of the Code and the observed fatigue life of the tees will be developed in a separate report.

5. SUMMARY AND CONCLUSIONS

This report, along with the materials contained in the appendixes, is a complete documentation of a series of experimental elastic-response stress analyses and low-cycle fatigue-to-failure tests of five 12-in. ANSI Standard B16.9 forged piping tees that were made by three of the major suppliers of piping products to the U.S. nuclear power industry. The objectives of the study were to provide sufficient baseline structural response-to-load information to enable evaluation and/or improvements to the current ASME Code design rules and criteria for nuclear power plant piping system tees.

The test assemblies for each of the five tees, which were constructed by attaching segments of standard-size pipe to the tees with nuclear-quality welds, were instrumented with about 220 three-gage strain rosettes and loaded with 13 different loadings in the elastic-response range, including internal-pressure and direct force and bending-moment loads applied to the ends of the pipe extensions. An attempt has been made to present the experimental results in a manner that will serve the needs of research workers with various interests. For those interested primarily in experimental techniques, complete sets of specifications for constructing and testing the assemblies as well as complete documentation of the materials and procedures used in the tests have been included in the appendixes.

For those readers needing experimental benchmark data for comparison with either theoretical or other experimental stress analysis studies, detailed listings of the measured strains and calculated principal stresses, directed stress components, and stress intensities, as well as precise strain gage location data, have been included in the appendixes. The strain gage location data may also be used to provide a rather detailed description of the model geometry.

Results from the elastic-response tests are also presented graphically in the form of stress-intensity contour plots and selected line plots of the stress intensity as a function of gage position. These figures give a detailed description of the elastic-stress distributions over the body of each tee as well as showing the locations and magnitudes of the maximum stresses for each of the 13 different loadings.

For those readers concerned primarily with stress indices and flexibility factors for Code-related design calculations, this study has normalized and summarized the maximum stress-intensity data for comparison with the Code indices and has included in the appendixes detailed load-displacement measurements from 16 dial indicators that were located on the pipe extensions during the elastic-response tests.

Results from the elastic-response tests of these particular five 12-in. ANSI B16.9 tees support the following observations. In general, the stress distributions for all the loadings were smooth and without steep gradients or sharp discontinuities, and the maximum stresses were located either at or very near one of the strain gages. These facts, in addition to the detailed analyses and numerous tests of the data, justify a very high confidence in the accuracy of the reported results.

As expected, the elastic response to internal pressure was essentially symmetric with respect to the transverse plane for all the tees, but different response characteristics were observed, due primarily to local differences in the shape of the tees. Although geometric symmetry is important, the most important geometric variable appears to be the external surface radius of curvature at the transition between the branch and the run outlets. This was manifested by the higher maximum stresses for the tees made by manufacturer I as compared with those made by the other two manufacturers.

The highest maximum normalized stress intensities for all the tees resulted from axial loads on the branch. A direct comparison between the numbers for axial loads and bending loads is misleading, however, because of the different normalizing factors. Transverse-force loads and bending-moment loads gave comparable results for both the branch and run loadings to within 10% to 15% except for in-plane loadings on the run of T-7, for which the difference was about 35%. These results support the current design practice of ignoring transverse shear but suggest that perhaps axial thrust loads should be considered. Firm conclusions regarding the adequacy of the stress indices for Class 1 piping system tees given in the Code cannot be made until the experimental data are studied further and data from other tests are included. This will be done in a separate report.

After the elastic-response tests were completed and the data were reduced and examined for acceptability, each tee assembly was fatigue tested to failure with either an in-plane or an out-of-plane bending-type force load on the branch pipe, depending on which produced the highest maximum stresses. Tee No. T-7 was fatigue tested with an in-plane loading, and the other tees were fatigue tested with an out-of-plane loading. Each test assembly was pressurized to its nominal design pressure, and the maximum branch-pipe displacements were fixed throughout the tests.

During the fatigue tests, each test assembly was loaded with an alternating bending stress nominally equal to about $\pm 83,400$ psi (elastic equivalent) for an expected fatigue life of about 7,000 cycles, based on Markl's correlation. The maximum strain ranges were measured for the first 10 cycles to ensure shakedown, and the test assemblies were periodically examined with a liquid dye penetrant to determine the approximate number of cycles for crack initiation. Numerous photographs of the developing fatigue cracks were taken until the tee failed. After failure, the pipe extensions were cut off, and the inside surface of the tees was inspected using a dye penetrant and then photographed, after which the tees were returned to ORNL.

The dye-penetrant examinations showed that for every model except T-6, crack initiation and eventual failure occurred as expected in the vicinity of the most highly stressed region. The fatigue behavior of T-6 was anomalous in several respects, and therefore the tee and crack surface were metallurgically examined at ORNL. No apparent reasons for the anomalous fatigue behavior were discovered.

In addition to the fatigue failure data, some information was obtained on crack initiation and shakedown strain range that may be of value for further study. The fatigue test results as well as the elastic-response test results will be used in a separate study to assess the current ASME Code design procedures for nuclear power plant piping systems.

ORNL, Oak Ridge, Tennessee

Subject: Experimental Stress Analysis of ASA Standard B16.9 Tees
Project: Design Criteria for Nuclear Service Piping, Pumps, and Valves
(AEC Activity No. 04 60 80 03 1)

2-1-2. USAS B31.7, "Nuclear Power Piping," dated Feb. 1968.

2-1-3. "Section IX, ASME Boiler and Pressure Vessel Code."

1. SCOPE:

This specification covers the experimental stress analysis (strain-gage tests and brittle lacquer tests) and fatigue-to-failure tests that are to be conducted on two ASA standard B16.9 tees. Two tees, a 12 x 12 x 12-in. Sch. 80 ASA B16.9 tee fabricated from ASTM 106 Grade B carbon steel and a 12 x 12 x 6-in. Sch. 40 ASA B16.9 tee fabricated from type 304L stainless steel, will be supplied by the company for testing.

The required tests are a portion of the joint AEC (ORNL) - PVRC program to develop stress indices and flexibility factors for piping components. Task No. 1 of the PVRC report, "Program and Request for Proposals for Development of Stress Indices and Methods for Analysis for Piping, Valves, and Pumps," dated July 1, 1967, is included for reference information.

Two quadrants of each tee shall be extensively strain gaged on both inside and outside surfaces to obtain the surface strain data necessary for the analysis. The seller is also to weld pipe stubs on each of the three connections to transmit force and moment loadings to the tee and to provide end closures for each of the three pipe stubs. Deflection or angular rotation measuring devices are to be installed in sufficient quantity and positions to determine the flexibility of the tee relative to a pipe of the same schedule and length as the tee. The brittle lacquer tests will be conducted prior to the strain-gage tests. Strain measurements will be taken with internal pressure loading and with 12 different moment and force loadings, as shown in Fig. 1 of the PVRC task description. The results of the strain-gage tests will be the basis of selection of the loading to produce fatigue failure in the low-cycle range (500 to 100,000 cycles).

All strain-gage readings, deflection measurements, load or force measurements, and an analysis of the data shall be submitted to the company.

2. APPLICABLE SPECIFICATIONS, STANDARDS, AND OTHER PUBLICATIONS:

2-1. General

The latest revision of the following documents shall form a part of this specification to the extent stated in subsequent sections.

2-1-1. Unnumbered PVRC report, "Program and Request for Proposals for the Development of Stress Indices and Methods for Analysis for Piping, Valves, and Pumps," dated July 1, 1967.

3. REQUIREMENTS:

3-1. It is the intent of this specification to describe work to be done to achieve the objectives of Phase A, Task No. 1, outlined in the reference under Section 2-1-1. A copy of Task No. 1 is included in Section 6-2 for reference information only. Where specific differences and requirements exist between this specification and those indicated in Task No. 1, considerations shall be given to this specification only.

3-2. Specimen and Test Assembly

3-2-1. Materials. Two tees - a 12 x 12 x 12-in. Sch. 80 ASA B16.9 tee fabricated from ASTM 106 Grade B carbon steel and a 12 x 12 x 6-in. Sch. 40 ASA B16.9 tee fabricated from type 304L stainless steel - will be supplied by the company. Pipe extensions of the same materials and of sufficient length to meet loading requirements shall be welded to the tees and the ends shall be closed for pressure containment. All end closures may be of carbon steel. Pipe legs shall be purchased to A106 Grade B and A312 TP 304L with a certified mill test report. The minimum and maximum inside diameter, outside diameter, and wall thickness at both ends of each leg and the weight of each leg shall be measured, recorded, and submitted as part of the data.

3-2-2. Alignment. Proper alignment limited only by irregularities in the geometry of the tee and pipe legs shall be maintained during welding of test assembly.

3-2-3. Welded Joints. The gas tungsten arc welding method shall be used for all welds in the fabrication and assembly of the test piece; that is, the tee-to-pipe stub welds and the attachment of the end closures. Materials shall comply with Chapter 1-III of USAS B31.7, Nuclear Power Piping, dated February 1968. The requirements of Chapter 1-V, USAS B31.7 for Class I Piping Systems, shall apply in the fabrication and assembly of the test piece.

Qualification of the welding procedures to be used and of the performance of the welders and welding operators shall comply with the requirements of Section 9 of the ASME Boiler and Pressure Vessel Code. These procedures are to be inspected and approved by qualified representatives of the company. Radiographic, dye penetrant, ultrasonic, and metallographic examination of welds shall be performed in addition to the requirements of Section 9 of the ASME Boiler and Pressure Vessel Code, in the qualification of the weld procedures and in the qualification of the welders. The type and

extent of the weld examination and the test of the welds in the test assembly shall conform to Table A.7 (a), A.7 (b), and A.7 (c) of Appendix A of USAS B31.7. The inclusions and porosity allowed shall not be greater than one-half in size and one-half in number of those amounts listed in Appendix B, Paragraph B-1-140, USAS B31.7. The three pipe-to-tee welds of the test assembly shall be ground smooth with the walls on the inside of the assembly and also on the outside so as to produce no surface discontinuities. Undercutting resulting from these welds will not be permitted.

3-3. Loadings and Loading Fixtures

3-3-1. Fixtures and Frame. It shall be the responsibility of the seller to design and provide adequate loading facilities to properly apply loads as specified herein.

3-3-2. Loadings. Thirteen different loadings shall be applied to each test assembly as indicated in Fig. 1 of Task No. 1 (Section 6.2). All forces to accomplish these loadings (except internal pressure) shall be applied at a distance of four pipe diameters from the pipe-to-tee weld. The magnitude of the loadings shall be proposed by the seller and approved by the company. Strain shall be limited to 1000 $\mu\text{in./in.}$ at any gage point. The order of the loadings is discussed under test procedures (Section 3.9).

3-4. Instrumentation

Two full quadrants of the tee plus other discrete points on the assembly shall be instrumented, inside and outside, with a total of 225 three-gage strain rosettes. The company will supply the gage layout based upon the objectives of the program and the requirements dictated by other analyses with which the data will be compared. The type of gage may be chosen by the seller with approval of the company. Since gages may be required on or very close to the welds at the ends of the tee, the seller shall be prepared to weld short stubs to one or more of the tee outlets if necessary, prior to final placement of these inside gages.

3-5. Dial Gage Locations

Minimum requirements for dial gage locations are shown schematically in Section 6.3. Eight deflection measurements at each of two ends (Nos. 2 and 3) of the assembly shall be measured for each loading with respect to the fixed end (No. 1).

3-5-1. The lever arm, length L , should be such that with expected dial gage accuracy, the expected rotation can be measured with reasonable accuracy ($\pm 10\%$).

3-5-2. The reference frame to which the gages shall be attached should be connected to the pipe near end No. 1. The frame should be sufficiently rigid so that changes in dial and gage forces do not significantly affect the readings. While this force change may be only a few ounces, the frame will necessarily be quite long and, unless sufficiently rigid, may deflect significantly.

3-5-3. The measurement cross bars should be attached to the pipe at locations where local deformations of the pipe cross section are negligible. These attachments to the pipe should be as short as feasible (distance A , Fig. 6-3) because in evaluating the tee flexibility it will be necessary to subtract out the displacements due to the pipe; therefore it is necessary to know the pipe lengths accurately.

3-6. Brittle Coating Tests

After installation of inside gages and completion of the test assembly, a brittle coating test shall be performed to determine the location and orientation of outside principal stresses. The location and number of the outside gages will then be subject to review and possible adjustment. The procedure for the brittle coating tests shall generally conform to the following outline.

3-6-1. Each loading shall be applied successively to one-third the maximum scheduled loading to minimize the effects of residual stresses.

3-6-2. Brittle lacquer with a sensitivity of approximately 500 $\mu\text{in./in.}$ shall be applied to at least one-half of the tee.

3-6-3. Branch moments and branch forces shall be applied in succession beginning with M_{2x} . Each load shall be applied in increments until cracks occur in the brittle coating or until a previous crack pattern is intensified. Under no circumstances shall the load exceed one-half of the maximum scheduled loading level.

3-6-4. The second half of the tee shall then be coated and the run moments and run forces applied in the same manner beginning with M_{2x} .

3-6-5. The above procedure may be adjusted during testing if mutually agreed on by the seller and company representative.

3-7. Data Requirements

The following data and data analysis shall be submitted as indicated in Section 5.

H

Number: JS-115-229
Date: Jan. 17, 1969
Revised:
Page 5 of 8

Number: JS-115-229
Date: Jan. 17, 1969
Revised:
Page 6 of 8

3-7-1. The linear response of each gage in units of inches per inch per unit load determined by least squares fitting the data from each of the loading increments.

3-7-2. Elastically-calculated stresses and strains in the direction, and transverse to the direction, of a row of gages.

3-7-3. Elastically-calculated principal stresses and strains and their directions, ϕ_p , relative to a row of gages.

3-7-4. Graphical plots of the above quantities as a function of gage position.

3-8. Data Acquisition

3-8-1. Strain readings shall be taken from all gages and dial indicators at the beginning of each run and after each loading and unloading increment.

3-8-2. Strain readings at successive zero loads shall not differ from each other by more than ± 25 $\mu\text{in./in.}$ or $\pm 10\%$ of the maximum strain reading for that gage during that loading, whichever is smaller. In the event this requirement is not met for specific gages during the required number of loadings, additional loadings shall be run for these gages until compliance is met. If internal unrepairable gages persist in erratic or unsatisfactory behavior, a company representative will determine when a maximum effort has been made to obtain data from these gages.

3-9. Test Procedures

Following the brittle coating tests and the attachment of external instrumentation, each tee shall be tested with the prescribed loadings. The first load to be applied shall be M_{1x} followed by the remaining branch moments and branch forces. The same order shall apply for the run moments and run forces, beginning with M_{2x} . The internal pressure test may be interjected into the above order at any convenient time. For each loading the procedure used shall be as follows.

3-9-1. Each loading shall be applied to one-half of the programmed maximum load and a set of data taken. This data shall be scanned for points of maximum strain. In the event any strains indicate that, on maximum loading, the value of strain at that point will exceed the 1000 $\mu\text{in./in.}$ limit, the programmed maximum load shall be adjusted accordingly.

3-9-2. After confirming the adequacy of the maximum load, the test piece shall be loaded and unloaded until linear elastic behavior is achieved. Complete data need not be taken during this shakedown process; however, it provides ample opportunity to evaluate the stability of instrumentation.

3-9-3. The test piece shall then be loaded to the maximum load in four incremental steps. These steps shall be repeated on the unloading process making a total of nine sets of data for each loading, taken as indicated in Section 3-8.

3-9-4. The above test (3-9-3) shall be repeated and data for the two runs examined for compliance with requirements described in this specification.

3-10. Fatigue Tests

Each tee shall finally be tested to failure by fatigue loading. The company will select the loading to be used in the fatigue test upon completion of the elastic testing of each tee. The loading will be a moment applied to the branch; however, a decision on the direction, M_{1x} or M_{1z} , will not be made until sufficient data are received from the elastic tests.

In any event, the loading shall be made in a fully reversed cycle, maintaining a constant maximum displacement in each direction. The tee shall be hydraulically pressurized to 2250 psi internal pressure in the 12 x 12 x 12-in. Sch. 80 carbon steel tee test and to 1090 psi internal pressure in the 12 x 12 x 6-in. Sch. 40 type 304L stainless steel tee test. This pressure shall be held constant during the entire fatigue test.

The magnitude of the loading shall be proposed by the seller and approved by the company, and should be sufficient to cause a fatigue failure in the range between 500 and 100,000 cycles. Failure in this instance is defined as the first indication of a leak and shall cause the test to be terminated.

The test shall be interrupted at frequent intervals and inspected for signs of a developing fatigue crack. Dye-penetrant or fluorescent-magnetic particle inspections as applicable will be made to detect cracks on the outside surface. Suspected areas are to be photographed during each inspection and these photographs are to be considered a portion of the records of the test.

4. INSPECTIONS:

4-1. The company shall have access to the test site as necessary for observation of test preparations and tests.

4-2. The company shall be advised of the schedule of preparations and tests in sufficient time to allow an observer to be present for activities of interest.

5. REPORTING OF RESULTS AND RETURN OF SPECIMENS:

5-1. The following reports shall be submitted covering the work described herein.

5-1-1. Monthly Status Reports. These reports are due at the company on the first day of each month. They should cover the month's activities in sufficient detail so that portions can be abstracted by the company for inclusion in a program report to the AEC. Three copies of 8 1/2 x 11 in. glossy print photographs should be included as appropriate. A projection of the planned activities for the next month is to be included. The format for the report may be a letter or memorandum.

5-1-2. Quarterly Progress Reports. These reports are due at the company on the 10th day of each quarter, that is, January 10, April 10, July 10, and October 10. Fifteen copies are required. They are to be a general summary report covering the preceding three-month period; the first report may necessarily cover a shorter period. They need not contain all the specific details contained in the monthly reports but should present a clear description of the work, since these reports will be passed on unedited to AEC Headquarters and others on a limited, official use only, distribution. The format of the report is left to the discretion of the seller, but should contain an introduction and conclusions.

5-1-3. Final Topical Reports. Formal summary reports shall be submitted upon completing the elastic strain-gage analysis of each tee and upon completing each fatigue test. Data shall be included as both tabulated summaries and graphical plots. Fifty (50) copies of each are required. Drafts of the final reports shall be submitted to the company for approval and comment. The work shall be deemed completed upon receipt by the company of the final reports.

5-1-4. Informal Submission of Data. Data for each of the described loadings, including data obtained during test setup, shall be made available to the company immediately upon completion of acquisition and processing. The company is to be notified, in writing, that such data are available. However, transmittal to the company shall be made only upon request.

5-2. Following the completion of the fatigue tests, the extensions of the tees shall be cut and removed approximately 3 in. from the weld leaving the weld and tee intact. Gages and a portion of the lead wires shall be left on the specimen. The tees shall then be returned to the company for final disposition.

6. NOTES AND REFERENCES:

6-1. Suggested Contractual Features

6-1-1. Revised Loadings. It is anticipated that certain loadings may be repeated with combinations of moments and forces, for example, $F_{2y} \pm M_{2y}$; $F_{2z} \pm M_{2z}$; $F_{3z} \pm M_{3z}$; and $F_{3x} \pm M_{3x}$. The seller shall be prepared to perform these additional tasks if required. This shall be considered additional work and the additional cost negotiated with the company.

6-1-2. Addition or Deletion of Gages. The seller shall be prepared to add or delete as many as 25 three-gage rosettes from the number indicated in this specification. The quotation shall include the incremental cost increase or decrease for each rosette added or deleted.

6-2. Reference

TASK NO. 1

MEASUREMENTS OF SURFACE STRAINS AND
FATIGUE TESTS OF ASA B16.9 TEESScope

Table 1 lists the specific tee test specimens and fatigue test loading conditions.

Phase A consists of a thorough investigation of Items 4, 6, 8, and 15 of table. Phase B includes the remainder of the items of Table 1. Detailed test procedures for Phase B will be guided by the results of Phase A tests and possibly by the results of the theoretical analysis of tees performed under Task 4.

15	12x12x6	Sch 40	TP 304 or 304L	Moment	III	A

Part of the objective of this program is to determine the extent of the differences in stresses in tees of different manufacturers. Tees from three different manufacturers are to be included, indicated by I, II, and III of Table 1. The bidder shall specify the specific manufacturers. The tees purchased for the program should be typical of the manufacturers' products.

Strain measurements are to be taken with internal pressure and with the moment and force* loadings shown in Fig. 1.

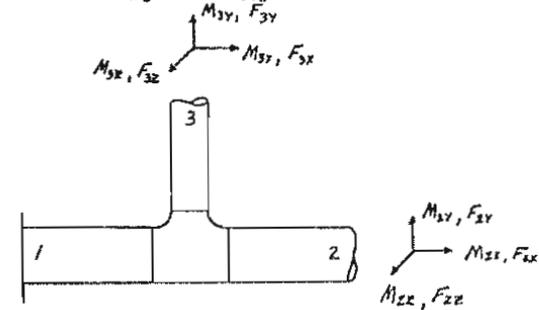

Fig. 1. Test Loadings for Strain-Gage Tests

Pressure and each of the six indicated moments are to be applied separately (seven separate loadings). Each test shall include strain-gage readings at a minimum of three load increments up and down through at least three cycles to insure that elastic states of strain are obtained. The bidder shall indicate what maximum loads he proposed to apply. Items 4 and 8 of Table 1 (Phase A) shall be thoroughly strain-gage instrumented and subjected to all indicated test loads to determine the critical areas where

* Force loadings are to be applied to Items 4 and 8 of Table 1. If stresses due to force loads are small compared to those due to moment loads, subsequent test models do not need to include force loads.

stresses due to the possible independent loadings can combine. It is expected that several hundred strain-gage elements will be required on each model, but the specific number and location of gages are to be specified by the bidder. The results of this investigation shall be used to locate critical regions on the other 11 models so that a smaller number of strain gages may be used.

For pressure fatigue tests, the pressure range will be determined on the basis of the strain-gage results. For moment-loading fatigue tests, both the moment (whether M_x , M_y , M_z , or some combination thereof and whether applied to branch or run) and its magnitude will also be determined from the strain-gage results. The air point will be between 500 to 100,000 cycles to failure. The fatigue tests shall be interrupted periodically for visual inspection to attempt to identify any crack initiation on the outside surface. All moment-loading fatigue tests shall be pressurized to the nominal design pressure, except Item 3 which shall be pressurized about 2 to 5 psig. All fatigue tests shall terminate upon the beginning of leakage.

All tests shall be run at room temperature.

DESIRED RESULTS

- (1) Inspection data on test specimens.
- (2) Strain-gage data converted to principal stresses, tabulated against load steps.
- (3) Fatigue test loadings and cycles-to-failure.
- (4) Description of the fatigue failure and crack initiation, if the crack initiation is detected on the outside surface.
- (5) Description of test procedures and discussion of accuracy of the test results.

ORNL, Oak Ridge, Tennessee

Subject: Experimental Stress Analysis of ASA Standard B16.9 Tees
Project: Design Criteria for Nuclear Service Piping, Pumps, and Valves
(AEC Activity No. O-60 89 03 1)

1. SCOPE:

This specification covers the experimental stress analysis (strain-gage tests and brittle lacquer tests) and fatigue-to-failure tests that are to be conducted on one ASA standard B16.9 tee. This tee, a 12" x 12" x 12-in. schedule 160 ASA B16.9 tee fabricated from type 304L stainless steel, will be supplied by the Company for testing.

The required tests are a portion of the Joint AEC (ORNL) - EVRC program to develop stress indices and flexibility factors for piping components. Task No. 1 of the EVRC report, "Program and Request for Proposals for Development of Stress Indices and Methods for Analysis for Piping, Valves, and Pumps," dated July 1, 1967, is included for reference and information.

Two quadrants of the tee shall be extensively strain gaged on both inside and outside surfaces to obtain the surface strain data necessary for the analysis. The Seller is also to weld pipe stubs on each of the three connections to transmit force and moment loadings to the tee and to provide end closures for each of the three pipe stubs. Deflection or angular rotation measuring devices are to be installed in sufficient quantity and positions to determine the flexibility of the tee relative to a pipe of the same schedule and length as the tee. The brittle lacquer tests will be conducted prior to the strain-gage tests. Strain measurements will be taken with internal pressure loading and with 12 different moment and force loadings, as shown in Fig. 1 of the EVRC task description. The results of the strain-gage tests will be the basis of selection of the loading to produce fatigue failure in the low-cycle range (500 to 100,000 cycles).

All strain-gage readings, deflection measurements, load or force measurements, and an analysis of the data shall be submitted to the Company.

2. APPLICABLE SPECIFICATIONS, STANDARDS, AND OTHER PUBLICATIONS:

2-1. General

The latest revision of the following documents shall form a part of this specification to the extent stated in subsequent sections.

2-1-1. Unnumbered EVRC report, "Program and Request for Proposals for the Development of Stress Indices and Methods for Analysis for Piping, Valves, and Pumps," dated July 1, 1967.

2-1-2. USAS B31.7, "Nuclear Power Piping," dated January 1969.

2-1-3. "Section IX, ASME Boiler and Pressure Vessel Code."

3. REQUIREMENTS:

3-1. It is the intent of this specification to describe work to be done to achieve the objectives of Task No. 1, outlined in the reference under Section 2-1-1. A copy of Task No. 1 is included in Section 6-2 for reference information only. Where specific differences and requirements exist between this specification and those indicated in Task No. 1, consideration shall be given to this specification only.

3-2. Specimen and Test Assembly

3-2-1. Materials. One tee - a 12" x 12" x 12-in. schedule 160 B16.9 tee fabricated from type 304L stainless steel - will be supplied by the Company. Pipe extensions of the same material and of sufficient length to meet loading requirements, to be supplied by the Seller, shall be welded to the tees and the ends shall be closed for pressure containment. At the Seller's option, end closures may be of carbon steel. Pipe legs shall be purchased to ASME TP-304L with a certified mill test report. The minimum and maximum inside diameter, outside diameter, and wall thickness at both ends of each leg and the weight of each leg shall be measured, recorded, and submitted as part of the data.

3-2-2. Alignment. Proper alignment limited only by irregularities in the geometry of the tee and pipe legs shall be maintained during welding of the test assembly.

3-2-3. Welded Joints. The gas tungsten arc welding method shall be used for all welds in the fabrication and assembly of the test piece; that is, the tee-to-pipe stub welds and the attachment of the end closures. Materials shall comply with Chapter 1-III of USAS B31.7, Nuclear Power Piping, dated January 1969. The requirements of Chapter 1-V, USAS B31.7 for Class I Piping Systems, shall apply in the fabrication and assembly of the test piece.

Qualification of the welding procedures to be used and of the performance of the welders and welding operators shall comply with the requirements of Section 9 of the ASME Boiler and Pressure Vessel Code. These procedures are to be inspected and approved by qualified representatives of the Company. Radiographic, dye penetrant, ultrasonic, and metallographic examination of welds shall be performed in addition to the requirements of Section 9 of the ASME Boiler and Pressure Vessel Code, in the qualification of the weld procedures, and in the qualification of the welders. The type and extent of the weld examination and the test of the welds in the test assembly shall conform to Table A.7 (a), A.7 (b), and A.7 (c) of Appendix A of USAS B31.7. The three pipe-to-tee welds of the test assembly shall be ground smooth with the walls on the inside of the assembly and also on the outside so as to produce no surface discontinuities. Undercutting resulting from these welds will not be permitted.

3-3. Loadings and Loading Fixtures

3-3-1. Fixtures and Frames. It shall be the responsibility of the Seller to design and provide adequate loading facilities to properly apply loads as specified herein.

3-3-2. Loadings. Thirteen different loadings shall be applied to the test assembly as indicated in Fig. 1 of Tack No. 1 (Section 7-2). All forces to accomplish these loadings (except internal pressure) shall be applied at a distance of four pipe diameters from the pipe-to-tee weld. The magnitude of the loadings shall be proposed by the Seller and approved by the Company. Strain shall be limited to 1000 $\mu\text{in./in.}$ at any gage point. The order of the loadings is discussed under Test Procedures (Section 3-9).

3-3-3. Boundary Conditions. In order to provide boundary conditions for theoretical analysis (not a part of this specification), stiffening rings, or other means, or sufficient rigidity to maintain pipe circularity during application of the loads shall be fixed to the pipe extensions at the point of load application (four pipe diameters from the pipe-to-tee weld). They may be welded in place for the elastic strain-gage tests but should be removed, and any damage to the pipe extensions repaired before fatigue testing.

3-4. Instrumentation

Two full quadrants of the tee plus other discrete points on the assembly shall be instrumented, inside and outside, with a total of 225 three-gage strain rosettes. Reference marks (-) and (+) will have been placed on the tee by the Company to be used by the Seller in making the gage layouts according to the general guideline contained in Section 7-4. Gage positions shall be approved by the Company prior to installation. The type of gage may be chosen by the Seller with approval of the Company. Since gages may be required on or very close to the welds at the ends of the tee, the Seller shall be prepared to weld short stubs to one or more of the tee outlets if necessary, prior to final placement of these inside gages.

3-5. Dial Gage Locations

Minimum requirements for dial gage locations are shown schematically in Section 4-3. Eight deflection measurements at each of two ends (Nos. 2 and 3) of the assembly shall be measured for each loading with respect to the fixed end (No. 1).

3-5-1. The lever arm, length L , should be such that with expected dial gage accuracy, the expected rotation can be measured with reasonable accuracy ($\pm 10\%$).

3-5-2. The reference frame to which the gages shall be attached should be connected to the pipe near end No. 1. The frame should be sufficiently rigid so that changes in dial and gage forces do

not significantly affect the readings. While this force change may be only a few ounces, the frame will necessarily be quite long and, unless sufficiently rigid, may deflect significantly.

3-5-3. The measurement cross bars should be attached to the pipe at locations where local deformations of the pipe or a section are negligible. These attachments to the pipe should be as short as feasible (distance A, Fig. 7-3) because in evaluating the tee flexibility it will be necessary to subtract out the displacements due to the pipe; it is therefore necessary to know the pipe lengths accurately.

3-6. Brittle Coating Tests

After installation of inside gages and completion of the test assembly, a brittle coating test may be performed at the discretion of the Company to determine the location and orientation of outside principal stresses. The location and number of the outside gages will then be subject to review and possible adjustment. The procedure for the brittle coating tests shall generally conform to the following outline.

3-6-1. Each loading shall be applied successively to one-third the maximum scheduled loading to minimize the effects of residual stresses.

3-6-2. Brittle lacquer with a sensitivity of approximately 500 $\mu\text{in./in.}$ shall be applied to at least one-half of the tee.

3-6-3. Branch moments and branch forces shall be applied in succession beginning with M_{2x} . Each load shall be applied in increments until cracks occur in the brittle coating or until a previous crack pattern is intensified. Under no circumstances shall the load exceed one-half of the maximum scheduled loading level.

3-6-4. The second half of the tee shall then be coated and the run moments and run forces applied in the same manner beginning with M_{2x} .

3-6-5. The above procedure may be adjusted during testing if mutually agreed on by the Seller and Company representative.

3-7. Data Requirements

The following data and data analysis shall be submitted as indicated in Section 6. The methods and formulas used in the data analysis are to be approved by qualified representatives of the Company.

3-7-1. The linear response of each gage in units of inches per inch per unit load determined by least squares fitting the data from each of the loading increments.

3-7-2. Elastically-calculated stresses and strains, including shear terms, in the direction, and transverse to the direction, of a row of gages.

3-7-3. Elastically-calculated principal stresses and strains and their directions, ϕ_p , relative to a row of gages, and the maximum shear stresses and strains.

3-7-4. Graphical plots of the above quantities (3-7-2 and 3-7-3) as a function of gage position.

3-7-5. The data analyses required in Sections 3-7-1, 3-7-2, and 3-7-3 shall be made available to the Company in machine readable form, either punched cards or magnetic tape, in addition to the submissions required in Section 6.

3-8. Data Acquisition

3-8-1. Strain readings shall be taken from all gages and dial indicators at the beginning of each run and after each loading and unloading increment.

3-8-2. Strain readings at successive zero loads shall not differ from each other by more than ± 15 $\mu\text{in./in.}$ or 25% of the maximum strain reading for that gage during that loading, whichever is smaller. In the event this requirement is not met for specific gages during the required number of loadings, additional loadings shall be run for these gages until compliance is met. If internal unrepairable gages persist in erratic or unsatisfactory behavior, a Company representative will determine when a maximum effort has been made to obtain data from these gages.

3-9. Test Procedures

Following the brittle coating tests and the attachment of external instrumentation, the tee shall be tested with the prescribed loadings. The first load to be applied shall be M_{max} followed by the remaining branch moments and branch forces. The same order shall apply for the run moments and run forces, beginning with M_{rx} . The internal pressure test may be interjected into the above order at any convenient time. For each loading the procedure used shall be as follows.

3-9-1. Each loading shall be applied to one-half of the programmed maximum load and a set of data taken. This data shall be scanned for points of maximum strain. In the event any strains indicate that, on maximum loading, the value of strain at that point will exceed the 1000 $\mu\text{in./in.}$ limit, the programmed maximum load shall be adjusted accordingly.

3-9-2. After confirming the adequacy of the maximum load, the test piece shall be loaded and unloaded until linear elastic behavior is achieved. Complete data need not be taken during this shakedown process; however, it provides ample opportunity to evaluate the stability of instrumentation.

3-9-3. The test piece shall then be loaded to the maximum load in four incremental steps. These steps shall be repeated on the unloading process making a total of nine sets of data for each loading, taken as indicated in Section 3-8.

3-9-4. The above test (3-9-3) shall be repeated and data for the two runs examined for compliance with requirements described in this specification.

4. FATIGUE TESTS:

The tee shall finally be tested to failure by fatigue loading. The Company will select the loading to be used in the fatigue test upon completion of the elastic testing. The loading will probably be a moment applied to the branch; however, a decision will not be made until sufficient data are received from the elastic tests. In any event, the loading shall be made in a fully reversed cycle, maintaining a constant maximum displacement in each direction. The tee shall be hydraulically pressurized to 3750 psi internal pressure. This pressure shall be held constant during the entire fatigue test.

The magnitude of the loading shall be proposed by the Seller and approved by the Company, and should be sufficient to cause a fatigue failure in the range between 500 and 100,000 cycles. Failure in this instance is defined as the first indication of a leak and shall cause the test to be terminated.

The test shall be interrupted at frequent intervals and inspected for signs of a developing fatigue crack. Dye penetrant or fluorescent-magnetic particle inspections as applicable will be made to detect cracks on the outside surface. Suspected areas are to be photographed during each inspection and these photographs are to be considered a portion of the records of the test.

5. INSPECTIONS:

5-1. The Company shall have access to the test site as necessary for observation of test preparations and tests.

5-2. The Company shall be advised of the schedule of preparations and tests in sufficient time to allow an observer to be present for activities of interest.

6. REPORTING OF RESULTS AND RETURN OF SPECIMENS:

6-1. The following reports shall be submitted covering the work described herein.

111

6-1-1. Monthly Status Reports. These reports are due at the Company on the first day of each month. They should cover the month's activities in sufficient detail so that portions can be abstracted by the Company for inclusion in a program report to the AEC. Three copies of 8 1/2 x 11-in. glossy print photographs should be included as appropriate. A projection of the planned activities for the next month is to be included. The format for the report may be a letter or memorandum.

6-1-2. Quarterly Progress Reports. These reports are due at the Company on the 10th day of each quarter, that is, January 10, April 10, July 10, and October 10. Twenty copies are required. They are to be a general summary report covering the preceding three-month period; the first report may necessarily cover a shorter period. They need not contain all the specific details contained in the monthly reports but should present a clear description of the work, since these reports will be passed on unedited to AEC Headquarters and others on a limited, official use only, distribution. The format of the report is left to the discretion of the Seller, but should contain an introduction and conclusions.

6-1-3. Final Topical Reports. Formal summary reports shall be submitted upon completing the elastic strain-gage analysis of the tee and upon completing the fatigue test. Data shall be included as both tabulated summaries and graphical plots. Fifty (50) copies of each are required. Drafts of the final reports shall be submitted to the Company for approval and comment. The work shall be deemed completed upon receipt by the Company of the final reports.

6-1-4. Informal Submission of Data. Data for each of the described loadings, including data obtained during test setup, shall be made available to the Company immediately upon completion of acquisition and processing. The Company is to be notified, in writing, that such data are available. However, transmittal to the Company shall be made only upon request.

6-2. Following the completion of the fatigue tests, the extensions of the tees shall be cut and removed approximately 3 in. from the weld leaving the weld and tee intact. Gages and a portion of the lead wires shall be left on the specimen. The tees shall then be returned to the Company for final disposition.

7. NOTES AND REFERENCES:

7-1. Suggested Contractual Features

7-1-1. Revised Loadings. It is anticipated that certain loadings may be repeated with combinations of moments and forces, for example, $F_{2y} \pm M_{2y}$; $F_{2z} \pm M_{2z}$; $F_{3z} \pm M_{3z}$; and $F_{3x} \pm M_{3x}$. The Seller shall be prepared to perform these additional tasks if required.

7-1-2. Addition or Deletion of Gages. The Seller shall be prepared to add or delete three-gage rosettes from the number indicated in this specification, up to a maximum of ± 25 .

7-3. Optional Fatigue Test. Upon completion of the elastic strain-gage test the Company may elect as an option to have the Seller conduct the fatigue test as specified herein unless indicated otherwise by the Seller.

7-1-4. Optional Brittle Coating Tests. The brittle coating tests may be deleted at the Company's discretion if information from other portions of the program should indicate that they are unnecessary. The Seller shall be prepared to delete these tests if required.

TASK NO. 1
MEASUREMENTS OF SURFACE STRAINS AND
FATIGUE TESTS OF ASA B16.9 TEES

Scope

Table 1 lists the specific tee test specimens and fatigue test loading conditions.

Phase A consists of a thorough investigation of Items 4, 6, 8, and 15 of table. Phase B includes the remainder of the items of Table 1. Detailed test procedures for Phase B will be guided by the results of Phase A test, and possibly by the results of the theoretical analysis of tests performed under Task 4.

Table 1. ASA B16.9 Tee Test Specimens and
Fatigue Test Loadings

Item No.	Nominal Size	Nominal Wall	Material	Fatigue Test Loading	Manufacturer	Phase
1	6x6x6	Sch 40	TP 304 or 304L	Moment	I	B
2	6x6x6	Sch 160	A-106-B	Pressure	I	B
3	6x6x6	Sch 40	TP 304 or 304L	Moment	I	B
4	12x12x12	Sch 80	A-106-B	Moment	I	A
5	12x12x12	Sch 80	A-106-B	Pressure	II	B
6	12x12x12	Sch 80	A-106-B	Moment	III	A
7	12x12x12	Sch 160	TP 304 or 304L	Moment	II	B
8	12x12x6	Sch 40	TP 304 or 304L	Moment	II	A
9	12x12x6	Sch 160	TP 304 or 304L	Pressure	II	B
10	24x24x24	Sch 40	A-106-B	Moment	III	B
11	24x24x24	Sch 160	A-106-B	Pressure	III	B
12	24x24x10	Sch 40	A-106-B	Moment	III	B
13	24x24x10	Sch 160	A-106-B	Pressure	III	B
14	12x12x6	Sch 40	TP 304 or 304L	UnDecided	I	B
15	12x12x6	Sch 40	TP 304 or 304L	Moment	III	A

Part of the objective of this program is to determine the extent of the differences in stresses in tees of different manufacturers. Tees from three different manufacturers are to be included, indicated by I, II, and III of Table 1. The bidder shall specify the specific manufacturers. The tees purchased for the program should be typical of the manufacturers' products.

Strain measurements are to be taken with internal pressure and with the moment and force* loadings shown in Fig. 1.

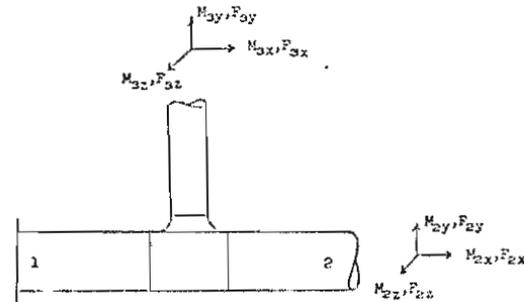

Fig. 1. Test Loadings for Strain-Gage Tests

Pressure and each of the six indicated moments are to be applied separately (seven separate loadings). Each test shall include strain-gage readings at a minimum of three load increments up and down through at least three cycles to insure that elastic states of strain are obtained. The bidder shall indicate what maximum loads he proposed to apply. Items 4 and 8 of Table 1 (Phase A) shall be thoroughly strain-gage instrumented and subjected to all indicated test loads to determine the critical areas where stresses due to the possible independent loadings

*Force loadings are to be applied to Items 4 and 8 of Table 1. If stresses due to force loads are small compared to those due to moment loads, subsequent test models do not need to include force loads.

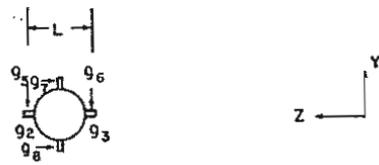

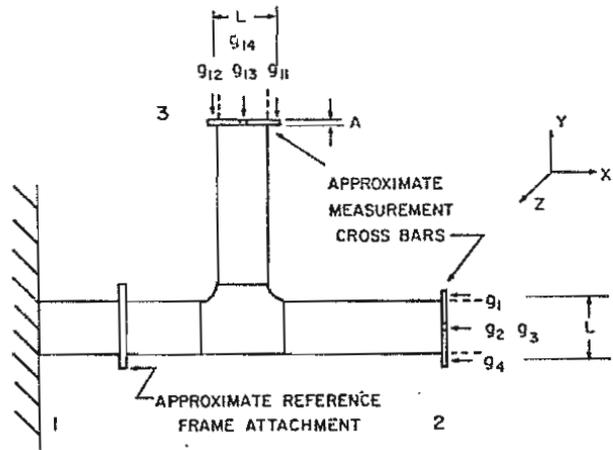

can combine. It is expected that several hundred strain-gage elements will be required on each model, but the specific number and location of gages are to be specified by the bidder. The results of this investigation shall be used to locate critical regions on the other 11 models so that a smaller number of strain gages may be used.

For pressure fatigue tests, the pressure range will be determined on the basis of the strain-gage results. For moment-loading fatigue tests, both the moment (whether M_x , M_y , M_z , or some combination thereof as whether applied to branch or run) and its magnitude will also be determined from the strain-gage results. The aim point will be between 500 to 100,000 cycles to failure. The fatigue tests shall be interrupted periodically for visual inspection to attempt to identify any crack initiation on the outside surface. All moment-loading fatigue tests shall be pressurized to the nominal design pressure, except Item 5 which shall be pressurized about 2 to 5 psig. All fatigue tests shall terminate upon the beginning of leakage.

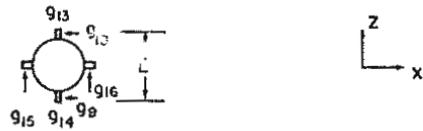

All tests shall be run at room temperature.

DESIRED RESULTS

- (1) Inspection data on test specimens.
- (2) Strain-gage data converted to principal stresses, tabulated against load steps.
- (3) Fatigue test loadings and cycles-to-failure.
- (4) Description of the fatigue failure and crack initiation, if the crack initiation is detected on the outside surface.
- (5) Description of test procedures and discussion of accuracy of the test results.

END VIEW OF 2

TOP VIEW OF 3

FIG. 7-3 DIAL GAGE LOCATIONS

STRAIN-GAGE LAYOUT GUIDELINES

1. Marks (-) have been made on the tee that establish the geometric axis of the run and of the outlet. Three cross marks (+) establish the intersection of the run and the nozzle as best as possible and the location of "bottom-dead-center" of the tee, and two cross marks (+) locate the root of the crotch (45° above the intersection of the centerlines of the run and branch).
2. An X-Y-Z coordinate system must be established with the identification cross marks (+) described in Item 1 above, clearly and accurately located in said system.
3. The center of each strain-gage rosette on the outside surface of the tee must be located in X-Y-Z coordinates. The lines along which the outside gages are located are also to be located in X-Y-Z coordinates.
4. The inside rosettes are to be located diametrically opposite the outside rosettes so that both rosettes at each location are normal to the "midplane surface" and aligned in the same direction to the best extent possible. The X-Y-Z coordinates of the inside rosettes are to be determined.
5. Two quadrants of the tee, (+X, +Y, +Z) and (-X, +Y, -Z) referenced to the coordinate system of Fig. 7-3, are to be strain gaged. Each of these quadrants is to be divided into 22 1/2° segments from the nozzle. The ϕ lines are located at 0°, 22 1/2°, 45°, 67 1/2°, and 90° from the centerline of the run of the tee as viewed from the nozzle. The crotch line is established by stretching a line between the cross mark (+) that marks the intersection of the nozzle and the run on the run horizontal midplane and the cross mark (+) that marks the crotch root. From the crotch line intersection the ϕ line is to be extended so that it crosses all run-circumferential lines at a constant angle. In the case of the 67 1/2° ϕ line this angle is 22 1/2°; the 45° ϕ line, it is 45°; and the 22 1/2° ϕ line, it is 67 1/2°.
6. Ten three-gage rosettes are to be placed along each ϕ line. They will be backed up by ten rosettes on the inside of the tee directly opposite them and aligned in the same direction. The first rosette on each ϕ line shall be placed over the center of the tee-to-nozzle stub weld. The ϕ lines are not to extend past the run midplane or past the run-to-tee weld. Exercise your judgement in spacing the rosettes along the ϕ lines with emphasis on the crotch region.
7. Along the crotch line, additional rosettes are to be placed inside and outside midway between the ϕ line intersections. These rosettes should be aligned along imaginary ϕ lines at these locations.
8. Inside and outside rosettes should be placed at the "bottom-dead-center" of the tee.
9. At approximate midpoints along each of the three stubs, gages should be placed at top-dead-center, bottom-dead-center, and at 90° to these gages. Two-gage, 90° rosettes can be used at these sites, provided that the gages are aligned along the axial and circumferential directions.

APPENDIX II

SwRI SCHEDULE FOR PREPARING AND CONDUCTING THE B16.9
STRESS ANALYSIS AND FATIGUE TESTS

The following general work schedule was adhered to although many of the tasks were performed simultaneously.

1. The test frames were designed.
2. Welding procedures and nondestructive inspection procedures were written and submitted to ORNL for approval.
3. Materials were ordered which were not readily available from stock in the quantities required. These included:

- (a) Strain gages - 900 three-gage 45° rosettes (MicroMeasurements EA-06-062RB-120, Option W for carbon steel and EA-09-062RB-120, Option W for stainless steel.)
- (b) Piping - 42 feet of 12-inch Schedule 80, A106 Grade B seamless, 30 feet of 12-inch Schedule 40 A312 TP 304L stainless, 19 feet of 6-inch Schedule 40 A312 TP 304L stainless.
- (c) Structural Steel - 20 tons of structural steel including: 336 feet of W12 x 85 beams; 48 feet of 15 x 3-1/2 channel; 56 feet of 8 x 8 x 1 angle; 280 square feet of 1-1/4 inch plate, and 654 square feet of 3/4 inch plate.
- (d) Welding supplies - including: 150 pounds each carbon steel and stainless steel rod for TIG welding and 50 feet each material EB consumable insert. All other rod and welding supplies used from stock in unknown quantities.

(The following items were ordered to make the T-7 modifications.)

- (e) 225 three-gage rosettes (MicroMeasurements EA-09-062RB-120, Option W).

- (f) A 14-foot length of A106 Grade B schedule 160 pipe.
- (g) 500 pounds of 308L stainless steel welding rod.
- (h) 2 tons of carbon steel plate for model end fixtures and frame modification.

4. Welders were qualified for model fabrication according to the approved procedures.

5. Test frame construction was completed and/or modified as necessary.

6. Strain gage rosette locations were established for the tee being tested, and XYZ coordinates were measured for each rosette.

7. Six-inch long pipe stubs were welded to the tee.

8. Strain rosettes were installed on the inside surface of the tee.

9. Model fabrication was completed.

10. The model was placed in a test frame and hydraulic jacks were arranged for the first loading mode to be applied.

11. A brittle lacquer test was conducted for selected loadings. (This test was not performed on T-6 and T-15.)

12. Strain rosettes were laid on the outside surface and dial indicators were installed.

13. Thirteen different loads were applied to the model in the order scheduled and deflection and strain data were recorded.

14. Strain data were transferred to IBM cards and transmitted to ORNL. Data were scanned concurrently using a duplicate set of IBM cards and the ORNL supplied computer program NOSEY (Reference 4) as a quality control measure.

15. After all data had been accepted by virtue of the acceptance criteria in the ORNL computer program for data scanning, a low-cycle fatigue test was conducted.

16. The model was removed from the test frame, the run and branch pipe were cut from the tee and the fabricated tee was returned to ORNL.

APPENDIX III

STRAIN GAGE LOCATIONS

This appendix presents graphical illustrations and tabulations of all strain gage locations. Figures III.1 through III.10 are computer displays showing the positioning and orientation of all rosettes. Tables III.1 through III.5 give the XYZ coordinates of the center of the number 2 gage on each rosette.

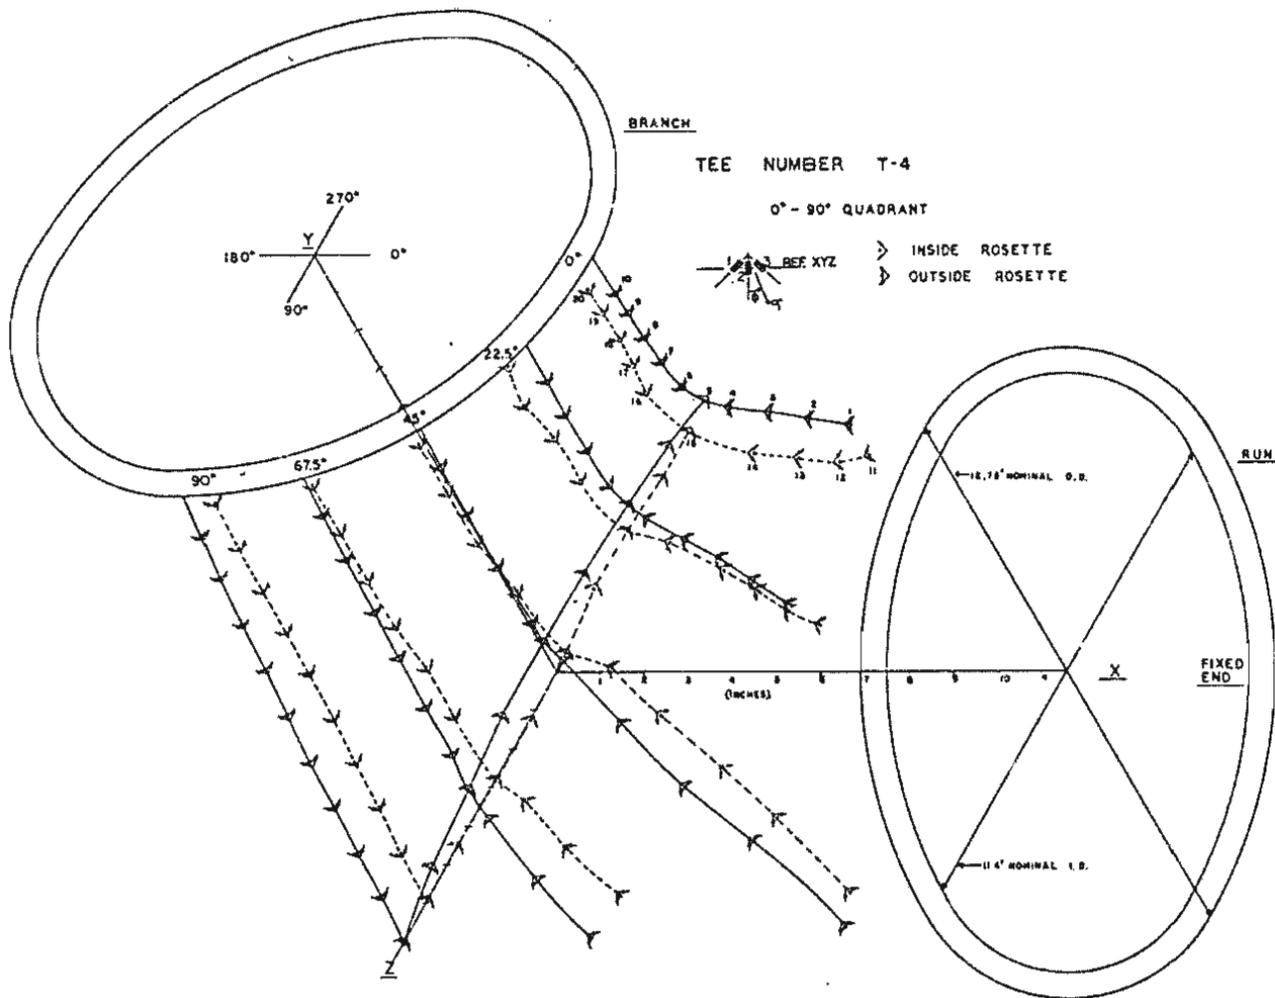

Figure III.1. Strain Gage Rosette Locations for the 0° - 90° Quadrant of Al06B Steel Tee Number T-4

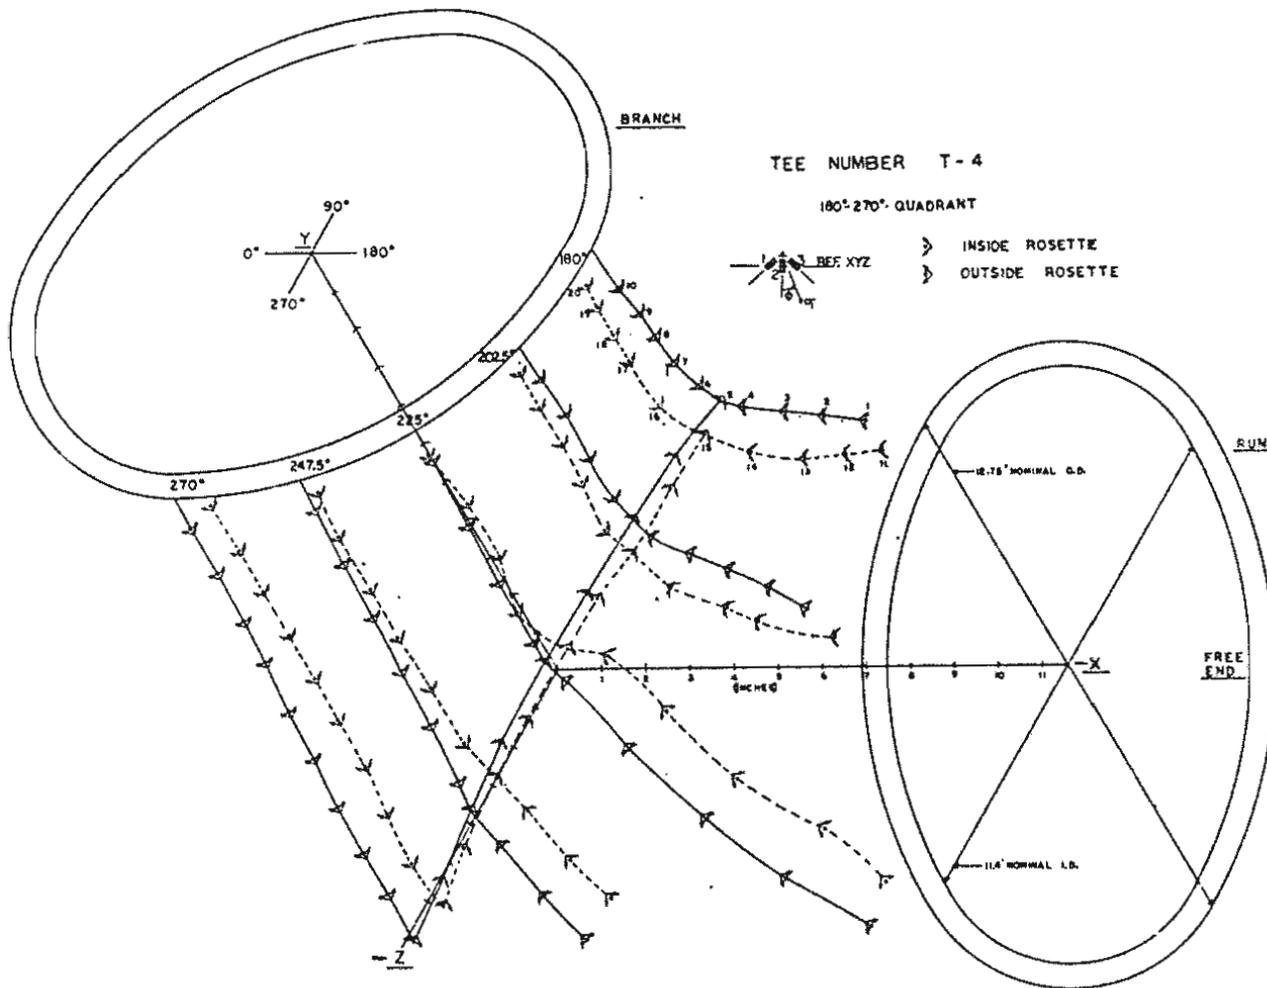

Figure III.2. Strain Gage Rosette Locations for the 180° - 270° Quadrant of A106B Steel Tee Number T-4

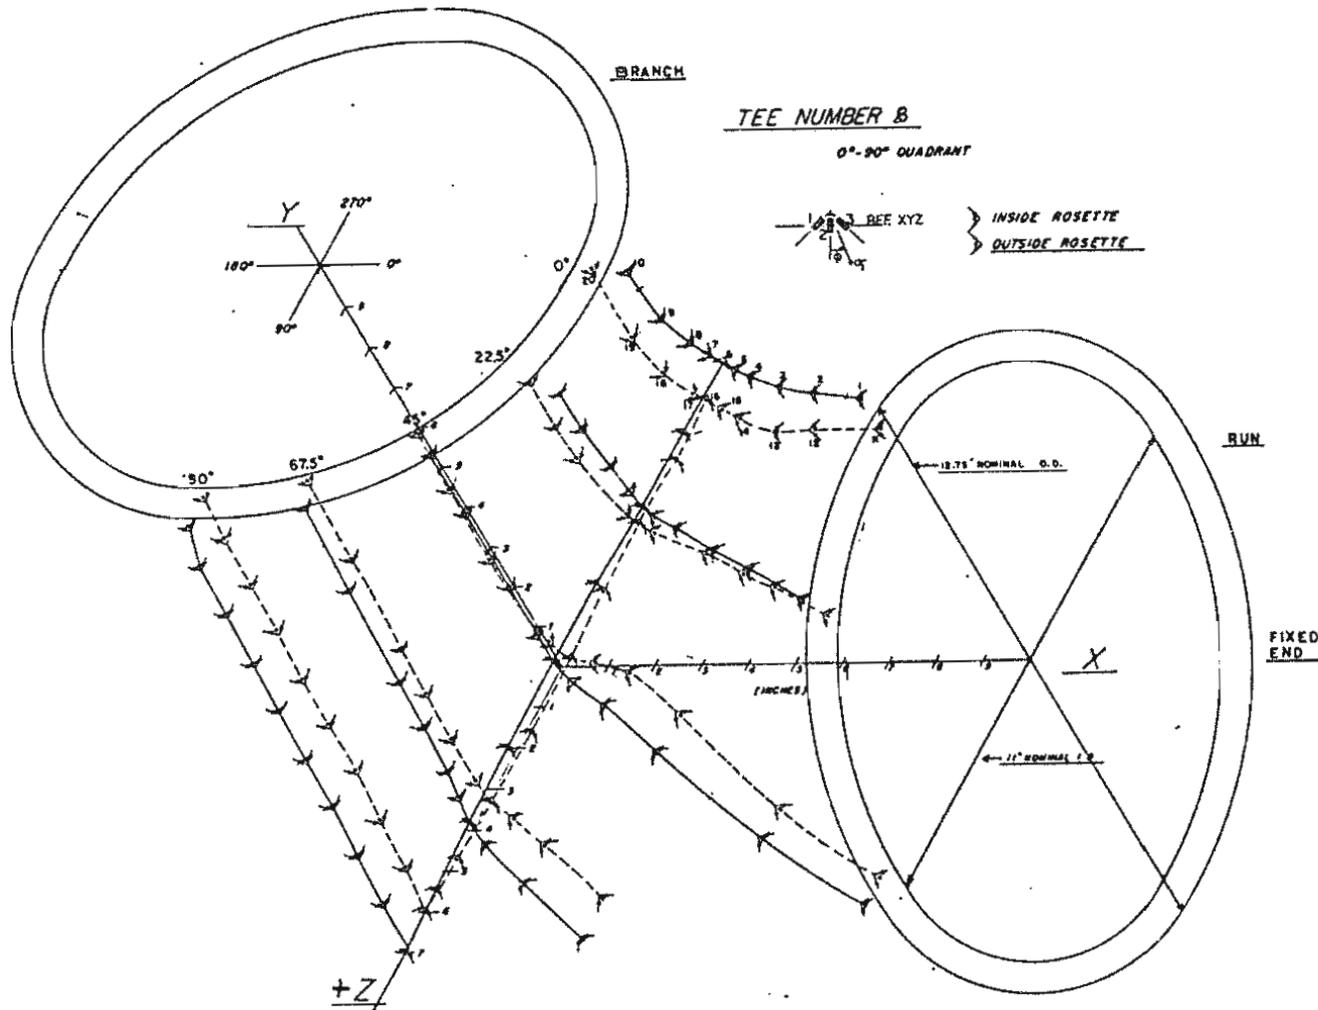

Figure III.3. Strain Gage Rosette Locations for the 0° - 90° Quadrant of T-6

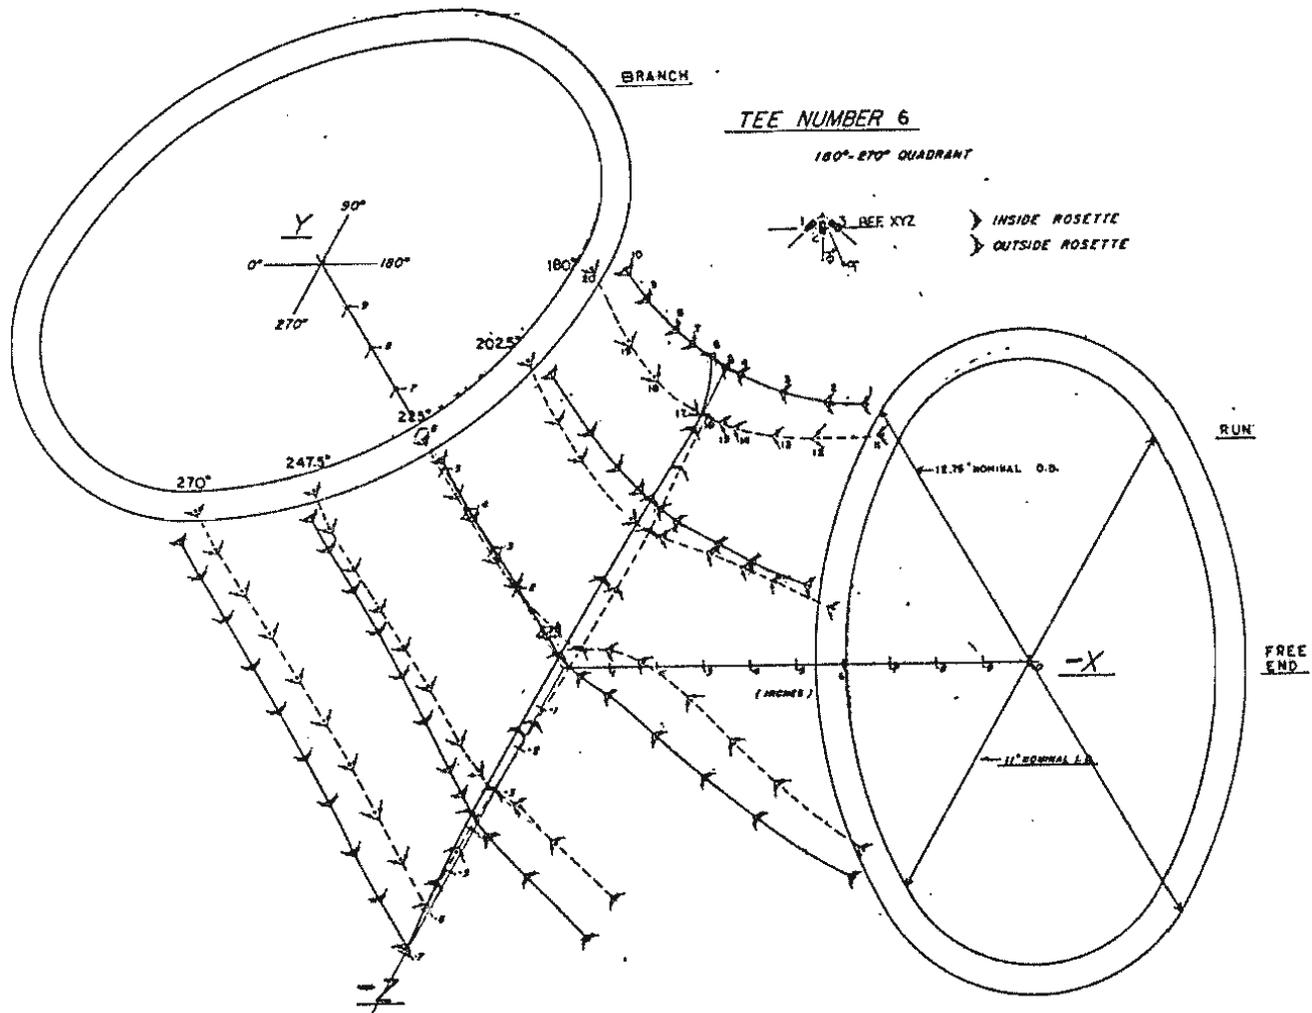

Figure III.4. Strain Gage Rosette Locations for the 180° - 270° Quadrant of T-6

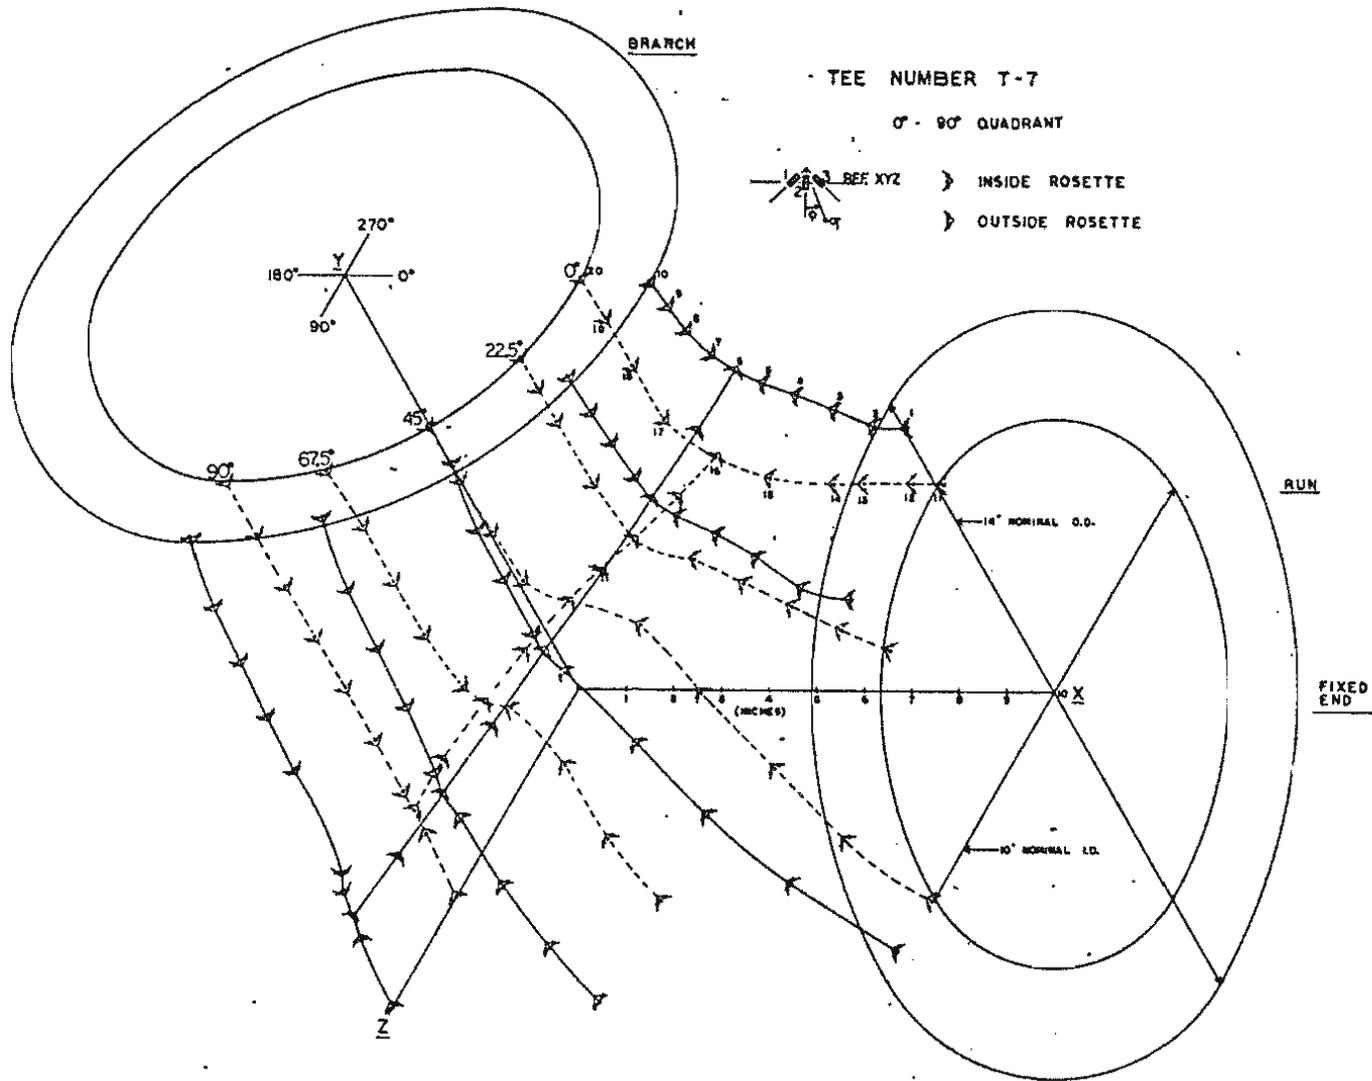

Figure III.5. Strain Gage Rosette Locations for the 0° - 90° Quadrant of T-7

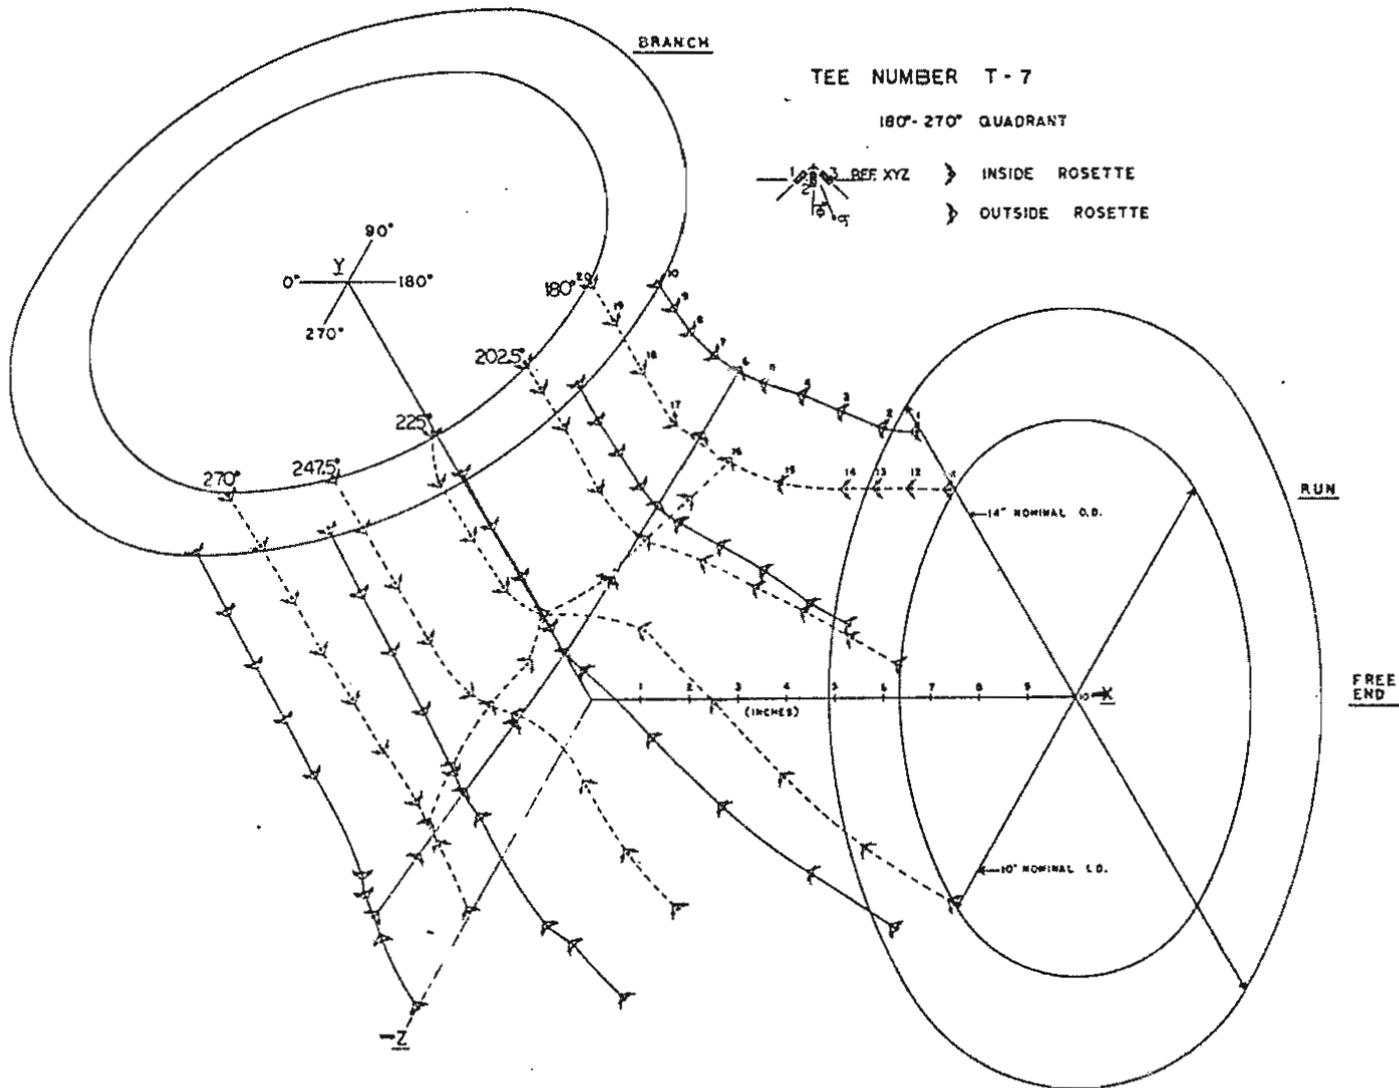

Figure III.6. Strain Gage Rosette Locations for the 180° - 270° Quadrant of T-7

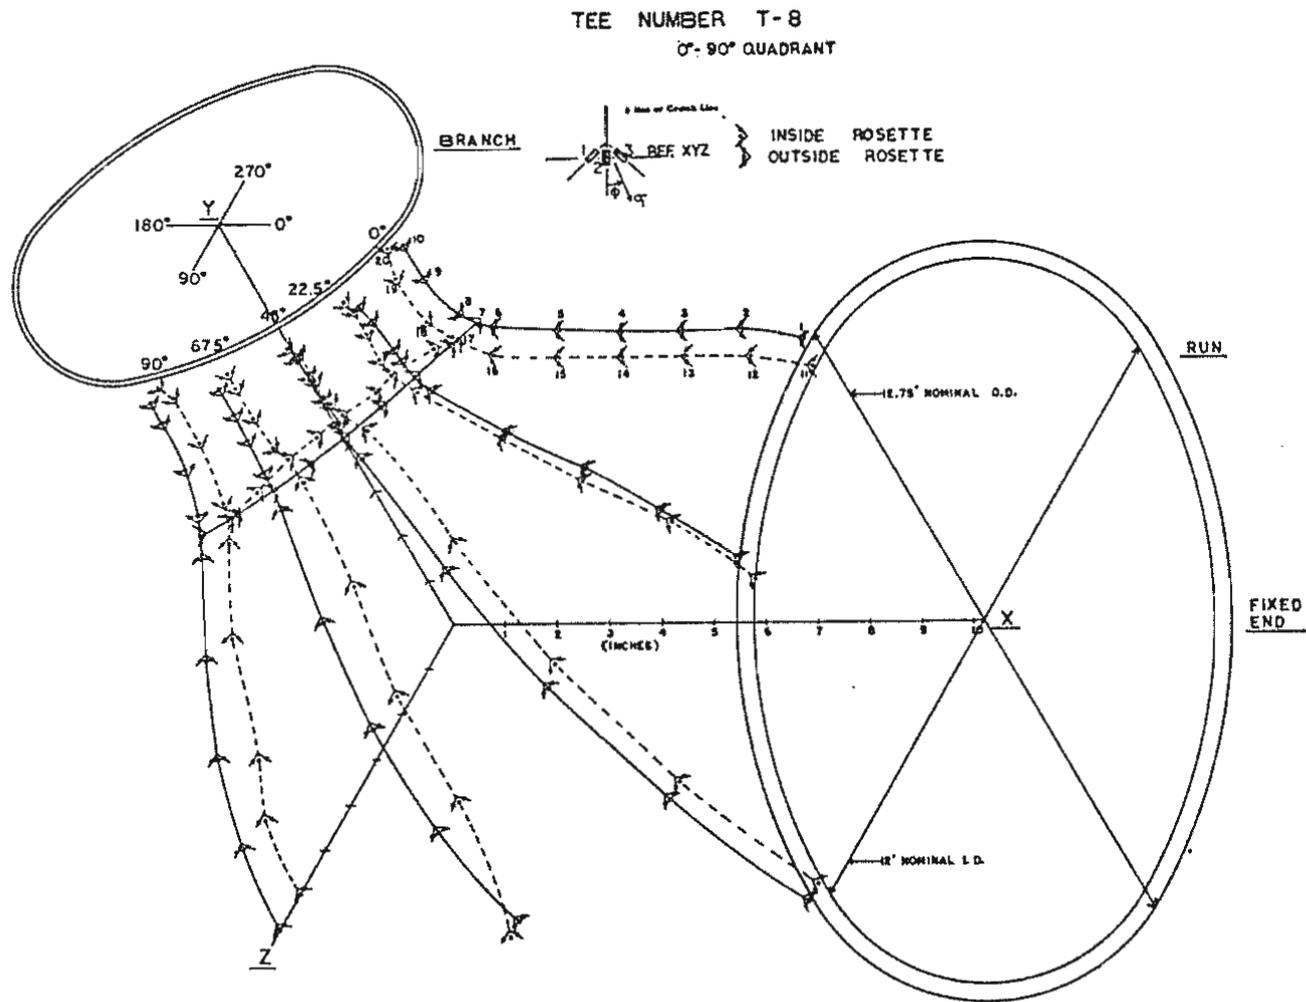

Figure III.7. Strain Gage Rosette Locations for the 0° - 90° Quadrant of T-8

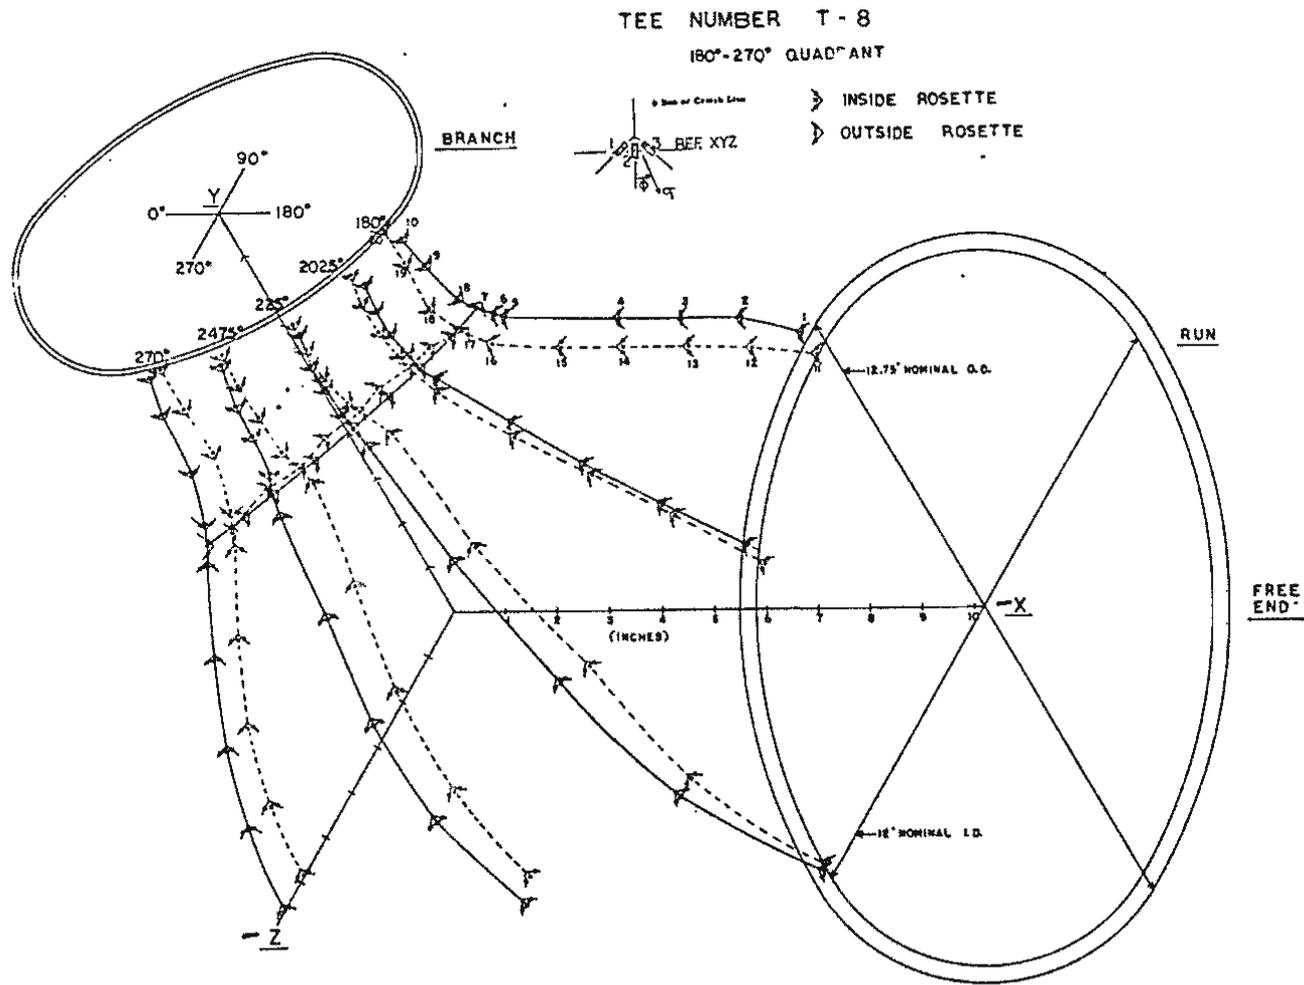

Figure III.8. Strain Gage Rosette Locations for the 180° - 270° Quadrant of T-8

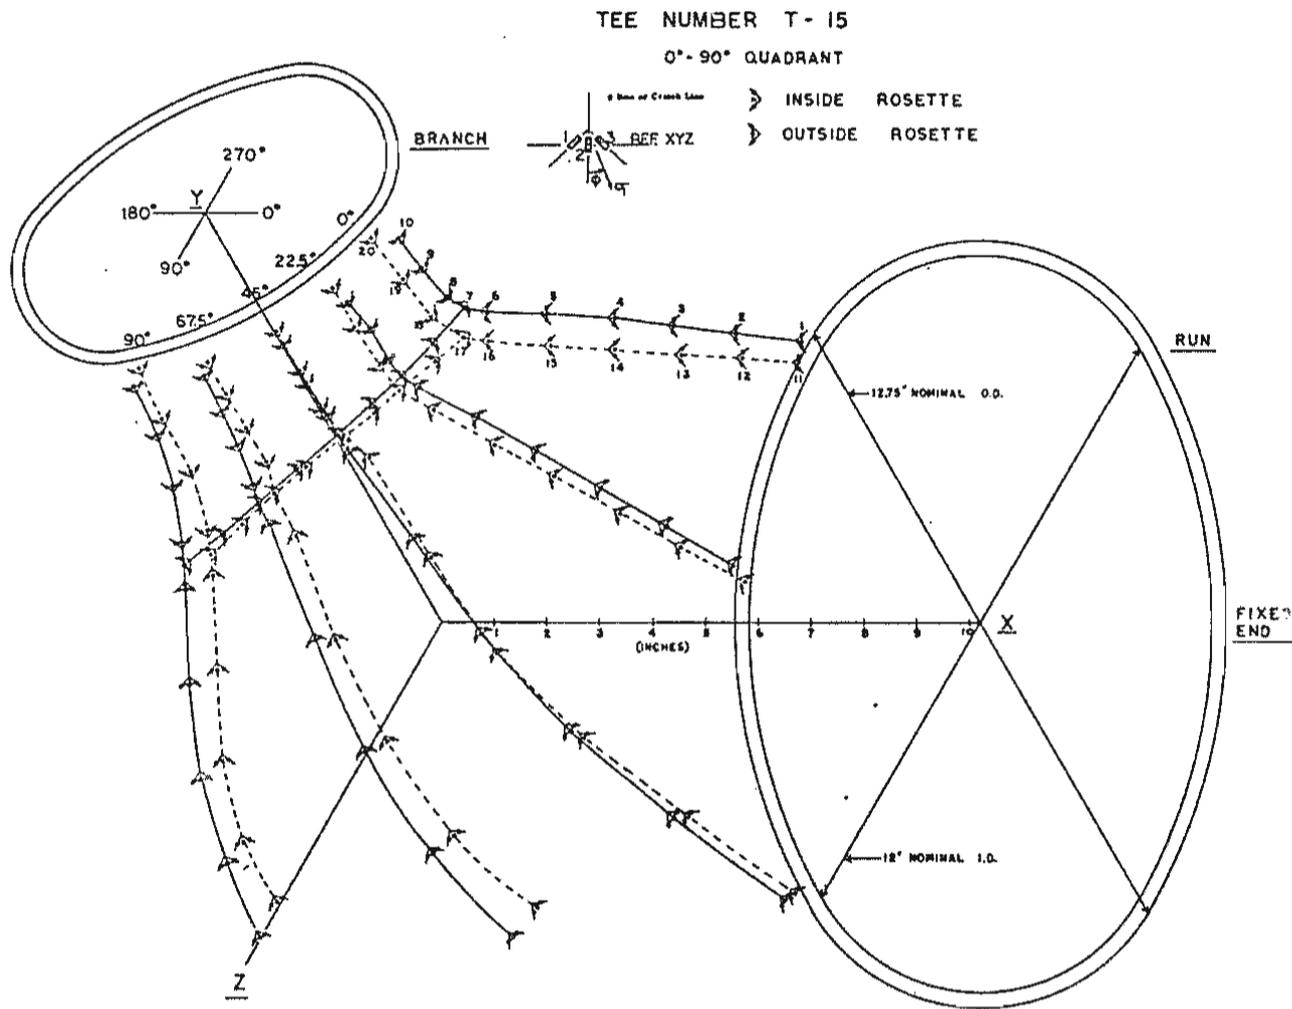

Figure III.9. Strain Gage Rosette Locations for the 0° - 90° Quadrant of T-15

APPENDIX IV
WELDING PROCEDURE SPECIFICATION

SWRI PROCEDURE FOR LIQUID PENETRANT INSPECTION OF
CLASS I NUCLEAR PIPING (PROCEDURE NO. P-1)

Scope

This procedure shall satisfy Paragraph 1-727.4.2.(c) 2 of USAS B31.7 for the penetrant inspection of critical circumferential welds in the scheduled test models. Acceptance standards shall be in accordance with Appendix B-4 of USAS B31.7.

This procedure shall also satisfy Paragraph 1-724.2.1 of USAS B31.7 for the penetrant inspection of welded base material in the scheduled test models. Acceptance standards shall be in accordance with Paragraph 1-724.1.4 of USAS B31.7.

Procedure

The test procedure shall be performed in accordance with Appendix B-4 of USAS B31.7 with penetration and development times as recommended in Procedure B-3 of ASTM E 165.

1. Method - A visible red dye penetrant method utilizing a solvent-removable penetrant free of chlorine and sulfur will be used with a volatile liquid suspended developer.

2. Surface Preparation - The surface to be inspected shall be ground flush with the surrounding material contour and shall be cleaned with Spotcheck Cleaner, Type SKC-S applied from a pressurized container. This cleaning will be completed when the surface to be inspected no longer contains dirt, lint, grease, scale, oil, or any other extraneous matter that would interfere with the test.

3. Drying - Prior to the application of the penetrant, the surface must be

dry. After cleaning the surface with the volatile solvent cleaner, a period of five minutes shall elapse before applying the penetrant to allow for the evaporation of the cleaner. Should it be necessary to facilitate evaporation, a heat gun (set on "cold") may be utilized.

4. Penetrant Application - The penetrant, Spotcheck Penetrant, Type SKL-HF shall be sprayed or brushed on the area being inspected. In either case, the penetrant will be taken from a pressurized container to insure its purity. The penetrant will be allowed to "dwell" on the inspection surface for a period of twenty minutes at room temperature surface conditions (maximum temperature range of 60° to 125°F).

5. Excess Penetrant Removal - After the specified penetrant dwell time, the excess penetrant shall be removed by wiping the area with dry lint-free wipes until the majority of the excess penetrant has been removed. Then an absorbent wipe will be moistened with the Spotcheck Cleaner, Type SKC-S and gently wiped across the inspection surface to remove the remaining traces of excess penetrant. Care shall be taken to not use an excessive amount of solvent cleaner, as it will remove penetrant from possible shallow open defect areas.

6. Drying - After the excess penetrant has been removed with the volatile solvent cleaner (Spotcheck Cleaner, Type SKC-S), the surface is allowed to dry for a period of five minutes.

7. Developing - The application of a liquid developer (Spotcheck Developer, Type SKD-S) shall follow the drying process. This developer will be applied by spraying from a pressurized container. After sufficient agitation of the pressurized container to insure a proper suspension of the developer powder, a smooth uniform

layer of the volatile suspended powder shall be applied to the test area.

8. Examination - The examination shall be performed by personnel with a minimum of three years' dye penetrant experience and in a well-lighted area. This examination will be performed within twenty minutes after application of the developer.

9. Acceptance Criteria

(a) Base Materials- The acceptance criteria for the inspected areas shall be the same as Paragraph 1-724.1.4 (b) in USAS B31.7 which states:

"Cracks and other linear discontinuities or aligned indications are unacceptable."

Aligned indications are those in which the average of the center-to-center distance between any one indication and the two adjacent indications in a straight line is less than 3/16 inch. Individual pit defects to a depth exceeding the greater of 0.004 inch or 5 percent of the section thickness are also unacceptable.

(b) Welds - Acceptance criteria for inspecting Class I piping welds constructed in accordance with sub-Section 1-727 of USAS B31.7 shall be as stated in Appendix B-4-170. The following relevant indications are unacceptable:

- (1) any cracks and linear indications
- (2) rounded indications with dimensions greater than 3/32 inch
- (3) four or more rounded indications in a line separated by 1/16 inch or less, edge to edge
- (4) ten or more rounded indications in any six square inches of surface whose minor dimension is no less than one inch with these dimensions taken in the most unfavorable location relative to the indications being evaluated.

10. Repair of Defects - When a repair is to be made according to the particular product form involving grinding with or without subsequent rewelding, that area shall be subjected to a repeat penetrant inspection utilizing the same procedure as previously outlined.

11. Post-Inspection Cleaning - The inspection areas shall be cleaned after the completed inspection by wiping the excess developer from the surface with a rag, and then gently scrubbing the region with an acetone-saturated wipe to remove the remaining developer and penetrant.

12. Records - Permanent records of the penetrant inspections shall be maintained in the file for the life of the component. These forms shall indicate the results and parameters for each test. A sample of the form to be used is shown in Appendix A. These forms shall be available for review upon request to the Department of Structural Engineering.

WELDER AND WELDING PROCEDURE QUALIFICATION
SPECIFICATION NUMBER Q-1

A. Scope

The qualification procedures herein are in accordance with Section IX of the ASME Code and Union Carbide Job Specification JS-115-229. Welders and procedures will be qualified for the 2G positions for both A106 Grade B pipe and A312 TP 304L pipe. The welder and procedures shall be qualified simultaneously. Qualifications in the 2G position qualifies the 1G position.

B. Types of Tests

1. Tensile Tests

Turned tensile specimens per Figure A-6 (c) of Section IX shall be used. The number of specimens shall be two (2) for each position and material per Table Q-13.1 of Section IX. The minimum allowable tensile strength shall be the minimum allowable for the base metal.

2. Bend Tests

Two (2) each face bend and root bend tests shall be performed for each position and material. The specimen design shall conform to Figure Q-7.2 of Section IX. Completed tests shall meet the requirements of Paragraph Q-8 (c) of Section IX except that allowable cracks in the carbon steel shall be limited to a single crack 3/32" long or a series of small cracks, the sum of the lengths not exceeding 3/32" and allowable cracks in the stainless steel shall be limited to a single crack 1/16" long or a series of small cracks, the sum of the lengths not exceeding 1/16".

3. Supplemental Tests

The qualification weld for a welder or welding procedure shall be 100% inspected by radiographs, dye penetrant or magnetic particle and ultrasonics. Inspection requirements shall be those specified in the welding procedures. In addition, two metallographic samples shall be cut from the weld.

4. Sampling

Test Specimens shall be cut from the qualification weld as shown in the attached figure.

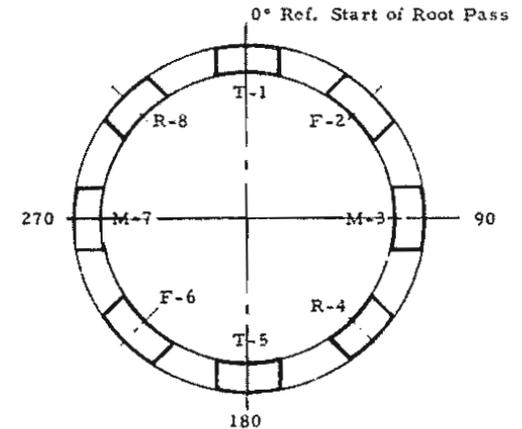

QUALIFICATION WELD SAMPLING PROCEDURE

T = Tensile Test

F = Transverse Face Bend

M = Metallographic Sample

R = Transverse Root Bend

IV-5

SWRI PROCEDURE FOR RADIOGRAPHIC INSPECTION OF 6-INCH
AND 12-INCH DIAMETER CIRCUMFERENTIAL PIPE WELDS
TO MEET CLASS I NUCLEAR PIPING REQUIREMENTS
(PROCEDURE NO. R-1)

1. Scope

This procedure shall satisfy Paragraph 1-724.2.1 of Specification USAS B31.7 and also Paragraph 1-727.4.2.(e). The methods for radiographic examination shall be in accordance with Appendix B-1 of USAS B31.7. The radiographic quality level shall satisfy Sub-Paragraph B-1-120.2.(e).

2. Personnel

- a. Personnel shall be trained and certified radiographers with a minimum of one year's experience.
- b. Isotope handling and radiation safety shall be in accordance with requirements of the AEC or appropriate State authority.

3. Equipment

- a. Isotope handling equipment will be approved by the AEC or appropriate State authority.
- b. Isotope used shall be Iridium 192; source dimensions not to exceed 1/8 inch by 1/16 inch.
- c. X-ray source shall have focal spot size not to exceed 1.3mm by 1.3mm.
- d. Processing darkroom shall be of adequate size for loading, processing, viewing, and storing film.
- e. Processing tanks shall have a minimum capacity of 5 gallons developer and fixer and 2-1/2 gallons short-stop solution.
- f. Clean running water shall be supplied to and flow around processing tanks and be used for washing films after development and fixing.
- g. A high-intensity viewer shall be available to analyze radiographs.
- h. Penetrators shall be according to the applicable requirements listed in Table B-1-110 of Specification USAS B31.7. Material may be carbon steel or stainless steel.

- i. Shim material shall be carbon steel or stainless steel as necessary.
- j. Letters and numbers for film identification, weld identification, etc., shall be as per Paragraph B-1-120.5 of Specification USAS B31.7.

4. Materials and Supplies

- a. Film shall be Kodak, Type M or finer grain as requested to attain required sensitivity.
- b. Intensifying screens shall be X-ray quality .005 -.010 inch lead, backed, and be free of scratches or other defects.
- c. Developer and fixer shall be Kodak X-ray or equal.
- d. Short stop shall be acetic acid-water bath of 1-200 concentration.
- e. Photoflo or equal shall be used as final film treatment before drying.

5. Processing Procedure

- a. Solution shall be between 68°F and 72°F and maintained at its temperature for 30 minutes before and during development, short stop, fixing, and washing.
- b. Film to be totally immersed and agitated continuously for the first minute in each solution and at least once a minute for the time recommended by the film and/or solution manufacturer.
- c. Film shall be kept on hangers until dry in lint and dust-free area. After drying, film shall be placed in protective packets.
- d. Dry film shall be handled with lint-free gloves only -- never with bare hands.
- e. Exposure conditions -- source-to-film distance, penetrometer placement, source information, number of film per shot, etc., shall be written on outside of packet or on an accompanying sheet identical to the one located in Appendix A of this procedure. A sketch of the radiographic setup shall be presented at the time of film interpretation.

6. Weld Surface Condition

The weld-ripples or weld-surface irregularities shall be removed on both inside and outside surfaces by any suitable mechanical process to such a

degree that the resulting radiographic contrast due to any irregularities cannot mask or be confused with the image of any objectionable defect. The weld surface shall merge smoothly into the base metal surface. The finished surface of the reinforcement of all butt-welded joints may be flush with the base metal or may have a reinforcement height compatible with that listed in Paragraph B-1-120.1, Appendix B, Specification USAS B31.7.

7. Number and Penetrator Placement

- a. Penetrators shall be in accordance with ASTM E 142.
- b. Identification letters shall be placed on external surface of pipe to identify film location. This identification shall be permanently located on pipe surface and identifiable on the film. The distance between adjacent letters is to be governed by the extreme source side penetrator placement as determined by the location of the source as indicated in Table B-1-120 (Penetrator Placement For Welds) of Specification USAS B31.7.
- c. A penetrator of the nominal wall thickness and a properly shimmed penetrator of the estimated total weld thickness shall be placed on each end of the area to be examined per exposure setup (3 penetrators equally spaced in the case of panoramic exposure). If a dissimilar thickness exists across the weld joint, penetrators applicable to both thicknesses shall be employed and shimmed to corresponding thickness. Penetrators shall have their major axis parallel to the weld centerline and shall not interfere with location of identifying markers or weld image. Shim thickness shall be equal to the difference between the thickness represented by the penetrator and the thickness of the material upon which the penetrator is placed. The shim shall in all cases be of the same or a radiographically similar material to that being inspected.
- d. Weld identification and other information as required by Paragraph B-1-120.5 of Specification USAS B31.7 shall be present on each film in an area not covered by the weld image.
- e. Identifying letters and numbers and penetrators are not to be fastened to film cassette.

8. Film and Source Placement

- a. Film cassettes shall be loaded with two films with "sandwich" construction of lead-film-lead-film-lead. Each film shall be in contact with lead screens on both surfaces.

- b. The film cassette shall be as close to the surface of the weld as practicable but in no case greater than 1/8 inch without qualifying extra distance from weld surface to film.
- c. The cassette shall be firmly fixed and maintained to surface of pipe by any suitable mechanical means.
- d. Source during exposure shall be maintained free of movement during exposure of film. For single wall exposures, source shall be positioned equidistant from all points of the weldment and in the plane of the weldment. For double wall exposures, the source shall be placed as close to the weld surface as possible and diametrically opposite to the center of the area to be viewed.

9. Film Quality Requirements

All radiographs shall be free from mechanical, chemical, or other processing defects that could interfere with proper interpretation of the radiograph, such as:

- a. Fogging
- b. Processing defects such as streaking or water marks
- c. Scratches, finger marks, crimps, dirtiness, static marks, smudges, or tears
- d. Loss of detail due to poor screen to film contact, false indications due to defective screens or artifacts caused by defective film.

10. Exposure

The exposure time shall be such as to produce a film density of 2.0 to 2.6 for each film in the region to be viewed. This density shall be evaluated by using a ASA density comparison strip.

11. Acceptance Standards

Any one of the following will be used as a basis for rejection of a weld.

- a. Any type of crack or zone of incomplete fusion or penetration
- b. Any elongated inclusion, such as slag or tungsten, that has a length greater than 1/8 inch for t up to 3/4 inch inclusive
- c. Any group of inclusions in line that have an aggregate length greater than 1/2t in a length of 12t except when the distance between the

SWRI PROCEDURE FOR ULTRASONIC INSPECTION OF 6-INCH AND 12-INCH
DIAMETER SEAMLESS AND WELDED (WITHOUT FILLER METAL)
PIPE TO MEET CLASS I NUCLEAR PIPING REQUIREMENTS
(PROCEDURE NO. UT-2)

1. Scope

This procedure shall satisfy Table A.7 (a) of Appendix A in Specification USAS B31.7. Additionally, this procedure shall satisfy Paragraph 1-724.1.1 of the same specification.

2. Personnel

Personnel utilized for this inspection shall be qualified ultrasonic inspectors having a minimum of 3 year's ultrasonic experience.

3. Equipment

Ultrasonic inspection equipment shall consist of the following.

- a. A commercially available pulse-echo ultrasonic unit such as a Sperry UM 721 or a Branson 301 A instrument
- b. Ultrasonic transducers having a cross section of $1/2 \times 3/4$ piezo-electric fabricated from polycrystalline ceramic material with a frequency of 2.25 MHz
- c. Required ultrasonic sensitivity standards
- d. Associated cables and couplant necessary for a manual ultrasonic inspection.

4. Basic Calibration

Machined notches on both the ID and OD surfaces of reference specimens with geometry and material similar to that scheduled for examination shall be utilized for standard reflectors. The size of the machined notches shall conform to Paragraph 1.724.1.1 (b) in which case the grooves placed on the ID and OD surfaces of the product shall not exceed one inch in length, have a width greater than one $1/16$ inch or a depth greater than the larger of .004 inches or 5 percent of the wall thickness. The reference specimen shall be long enough to eliminate edge effects during the inspection.

5. Surface Preparation

The surface to be inspected shall be maintained free of excess buildup of any nature that might hinder the incident sound as well as unnecessary

roughness arising from pitted conditions etc. The reference specimen shall have surface conditions similar to the specimen to be inspected.

6. Angle-Beam Method

An angle beam or shear wave inspection utilizing a 2.25 MHz polycrystalline ceramic transducer operated in a pulse-echo mode will be applied with the prime beam orientation propagating circumferentially around the pipe wall. The shear wave inspection will be applied from the OD surface utilizing a lucite wedge to generate a 45-degree shear wave within the material. This wedge will be coupled to the surface of the pipe by utilizing a contact technique and a commercially-available, water-soluble, couplant, (Hamkileer).

a. Calibration

Instrumentation calibration shall be accomplished by utilizing the reference specimen previously mentioned and establishing an amplitude of reflection from the respective longitudinally oriented notches on both the ID and OD surfaces. The magnitude of the amplitude of these reflections will be noted on the CRT screen presentation.

b. Examination Procedure

The examination of the base material of these components will be carried out by placing the shear wave transducer with the prime beam orientation circumferential around the piping and indexing laterally along the piping and circumferentially around the piping so as to cover all areas of base material with the shear wave, pulse-echo technique.

7. Acceptance-Rejection Criteria

The criteria utilized for rejection during this inspection shall be: all defects with greater indicated magnitude than the reference specimen shall be considered cause for rejection.

8. Repairs

All areas considered unacceptable on the basis of the reference specimen will be eliminated or repaired in accordance with Paragraph 1-724.1.6 and Paragraph 1-724.1.7 of Specification USAS B31.7.

9. Records

Permanent records of the inspection shall be kept on file by the

Department of Structural Engineering for the duration and life of the component. These forms shall reflect the results of the inspection as well as the parameters of the inspection. A sample of a typical form to be utilized is shown in the attached Appendix A. These records will be available for examination upon requesting permission from the Department of Structural Engineering.

IV-10

This procedure specification covers Scope and Carbon Steel Pipe-to-Tee and Pipe-to-Pipe Joint Weldments of the ASA Standard B16.9 Tee Test Specimens.

A. Base Metal

1. Tees - A-234 WPB Supplied by ORNL
2. Pipe - A106 Grade B

B. Filler Metal

1. Consumable Insert - EB Type "A" or "J", 1/8", 131
2. Bare Electrode - Linde Ox-Weld 65

C. Process

The closure pass shall be made by the Inert Gas-Tungsten Arc process, incorporating a consumable insert. All subsequent passes shall also be by the Inert Gas-Tungsten Arc process. All welding will be manual.

D. Gas for Inert Gas Welding

The shielding gas for the torch and backup shall be Argon, 99.995% pure.

E. Position

All pipe-to-tee weldments shall be made in the 2G position.

Pipe-to-pipe weldments shall be made in either the 1G or 2G position.

F. Preheat

No preheat will be used for carbon steel or stainless steel weldments.

Room temperature will be 70°F minimum.

G. Interpass Temperature

Due to possible thermal damage to the strain gages interpass temperature shall not exceed 350°F.

H. Post-Heat Treatment

None

I. Weld Finish

Pipe-to-tee weldment shall be ground flush on inside and outside surfaces to a 125 RMS finish. Pipe-to-pipe weldments will be ground flush on the outside surface.

J. Joint Design

The joint design at all joints will be a "V" groove with each bevel machined 37.5° to a diametral plane and contain a 1/32" maximum land. Pipe, weld caps and tees will be counterbored to obtain a round section and tapered to the original dimensions at a 4:1 slope. Mismatch at any point will be less than $\pm 1/32$ inch at the I.D. See enclosed drawing. Ref: USAS B31.7 Fig. 1-727.3.1(a).

K. Joint Preparation

1. Cleaning

All surfaces of the base metal, all filler wire, and the parts of any jigs or fixtures in contact with the joint or joint area shall be free of foreign materials. Immediately prior to fit-up and welding, an area 4 inches wide adjacent to the joint, and the joint edges shall be cleaned by brushing.

The base metal and backing bars shall be cleaned with Methyl Ethyl Ketone immediately prior to any tacking or welding operation. After cleaning, the joint area must not be touched by bare hands prior to welding.

2. Fit-up

The consumable insert shall be tacked into place in accordance with manufacturers recommended procedures. Tacks shall be cleaned by wire brushing. Additional tack welding utilizing the E. B. insert will be used to provide joint rigidity. All tacks must be back purged and cleaned (wire brushed) in accordance with the joint welding requirements.

L. Assembly and Fixtures

No temporary welded supports shall be attached to the pipe or tee. Pieces may be assembled and tack welded in the 2G position then placed in the 1G position for welding. The necessary fixtures will be provided to assure proper alignment and prevent undue stresses during welding.

M. Joint Welding Procedure

The closure pass and all subsequent passes shall be performed using the Inert Gas-Tungsten Arc process. The backside of the joint shall be shielded with Argon gas. Pre-purge shall be sufficient to eliminate excessive oxidation of the root passes. The consumable insert shall provide the filler metal for the root pass. Hand fed bare wire shall be used for all subsequent passes. See particulars in Table 1. To prevent cracking in the crater, fill crater and reduce weld pool to smallest possible size by down sloping current with auxiliary foot control.

All oxide (particles and film) from crater, weld beads, and base metal in the line of arc travel shall be removed before depositing each section of bead and from each completed weld bead.

Any cracks or blowholes that appear on the surface of any tack weld or bead of welding shall be removed by grinding.

All surface oxides must be removed by wire brushing or grinding before depositing the next successive bead of welding.

No peening or chipping of weld or base metal shall be allowed.

N. Welding Equipment

Current Source

Linde AC/DC High Frequency Welder, 500 amp. The current will be DC, straight polarity with electrode negative.

Welding Torch

Linde Model HW-20 (water cooled)

Current Control

Foot Control

O. Inspection

The Welding Inspector shall be the Research Assistant in charge of laboratory operation, the cognizant engineer or ORNL representative.

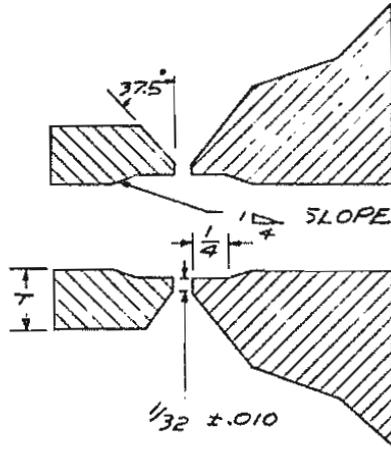

When the Welding Inspector believes inspection necessary, he will examine base metal or welds at any stage of fabrication, and when he has reason to question that this Procedure is being followed, the ability of the welder, or weld quality, he may require supplemental inspection, corrective action, or requalification of the welder.

P. Non-destructive Testing

The extent of the weld examination and the test of the welds in the test assembly shall conform to Table A. 7 (a), A. 7 (b), and A. 7 (c) of Appendix A of the USAS B31. 7. This examination includes 100% radiography, ultrasonic and dye penetrant or magnetic particle inspection. Procedures for radiographic, ultrasonic and penetrant inspection of the weldments shall conform to SwRI Specifications R-1, UT-1 and P-1 respectively.

SOUTHWEST RESEARCH INSTITUTE
WELDING PROCEDURE SPECIFICATION NO. W-3

-2-

This procedure specification covers Scope and Stainless Steel Pipe-to-Tee Joint Weldments of an ASA Standard B16.9 Tee Test Specimen, 12" x 12" x 12" Schedule 160.

A. Base Metal

1. Tee - A-403 TP 304L
2. Pipe - A312 TP 304

B. Filler Metal

1. Consumable Insert - EB Type "A" or "J", 1/8", 308L
2. Bare Electrode - ASME-SA-371, Type 308L
3. Covered Electrode - ASME-SA-298, Type 308L-16

C. Process

The closure pass shall be made by the Inert Gas-Tungsten Arc process, incorporating a consumable insert. A minimum of three subsequent passes shall be by the Inert Gas-Tungsten Arc process. Remaining passes shall be Metal Arc welding. All welding will be manual.

D. Gas for Inert Gas Welding

The shielding gas for the torch and backup shall be Argon, 99.995% pure.

E. Position

All pipe-to-tee weldments shall be made in the 2G position.

F. Preheat

No preheat will be used.

G. Interpass Temperature

Due to possible thermal damage to the strain gages interpass temperature shall not exceed 350°F.

H. Post-Heat Treatment

None

L. Weld Finish

Pipe-to-tee weldment shall be ground flush on inside and outside surfaces to a 125 RMS finish.

J. Joint Design

The joint design at all joints will be a "V" groove with each bevel machined 37.5° to a diametral plane and contain a 1/32" maximum land. Pipe, weld caps and tees will be counterbored to obtain a round section and tapered to the original dimensions at a 4:1 slope. Mismatch at any point will be less than ± 1/32 inch at the I. D. See Table 1. Ref: USAS B31.7 Fig. 1-727.3. 1(a).

K. Joint Preparation

1. Cleaning

All surfaces of the base metal, all bare filler wire, and the parts of any jigs or fixtures in contact with the joint or joint area shall be free of foreign materials. Immediately prior to fit-up and welding, an area 4 inches wide adjacent to the joint, and the joint edges shall be cleaned by brushing.

The base metal and backing bars shall be cleaned with Methyl Ethyl Ketone immediately prior to any tacking or welding operation. After cleaning, the joint area must not be touched by bare hands prior to welding.

2. Fit-up

The consumable insert shall be tacked into place in accordance with manufacturer's recommended procedures. Tacks shall be cleaned by wire brushing. Additional tack welding utilizing the E. B. insert will be used to provide joint rigidity. All tacks must be back purged and cleaned (wire brushed) in accordance with the joint welding requirements.

L. Assembly and Fixtures

No temporary welded supports shall be attached to the pipe or tee.

IV-18

M. Joint Welding Procedure

The closure pass and a minimum of three subsequent passes shall be performed using the Inert Gas-Tungsten Arc process. The backside of the joint shall be shielded with Argon gas. Pre-purge shall be sufficient to eliminate excessive oxidation of the root passes. The consumable insert shall provide the filler metal for the root pass.

Hand fed bare wire shall be used for subsequent passes incorporating the Inert Gas-Tungsten Arc process. When the TIG process is used, cracking in the crater will be prevented by filling the crater while down sloping the current with the auxiliary foot control in order to maintain the smallest possible weld pool. Particulars of rod size and amperage requirements are given in Table 1.

All remaining passes shall be made using covered electrode. Electrode size, number of passes and amperage requirements are given in Table 1.

All oxide (particles and film) from crater, weld beads, and base metal in the line of arc travel shall be removed before depositing each section of bead and from each completed weld bead.

Any cracks or blowholes that appear on the surface of any tack weld or bead of welding shall be removed by grinding.

All surface oxides must be removed by wire brushing or grinding before depositing the next successive bead of welding.

No peening or chipping of weld or base metal shall be allowed.

N. Welding Equipment

1. Inert Gas-Tungsten Arc Welding

Current Source

Linde AC/DC High Frequency Welder, 500 amp. The current will be DC, straight polarity.

Welding Torch

Linde Model HW-20 (water cooled)

Current Control

Foot Control

2. Metal Arc Welding

Current Source

Linde AC/DC High Frequency Welder, 500 amp. The current will be DC, reversed polarity.

O. Inspection

The Welding Inspector shall be the Research Assistant in charge of laboratory operation, the cognizant engineer or ORNL representative.

When the Welding Inspector believes inspection necessary, he will examine base metal or welds at any stage of fabrication, and when he has reason to question that this Procedure is being followed, the ability of the welder, or weld quality, he may require supplemental inspection, corrective action, or requalification of the welder.

P. Non-destructive Testing

The extent of the weld examination and the test of the welds in the test assembly shall conform to Table A. 7 (b) of Appendix A of the USAS B31. 7. This examination includes 100% radiography and dye penetrant inspection. Procedures for radiographic and penetrant inspection of the welds shall conform to SWRI Specifications R-1* and P-1,* respectively.

In addition, a radiographic inspection shall be made after completion of the root pass.

Q. Qualification

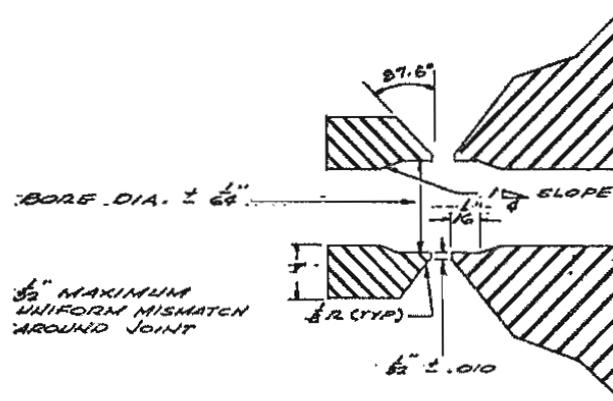

The welding procedure specification shall be qualified in accordance with requirements of ASME Band PV Code, Section IX. Prior to the removal of coupons for destructive examination,

*These specifications shall meet the requirements of Paragraphs B-1 and B-3 (respectively) of Appendix B, B31. 7.

the test weld shall be nondestructively examined as required for production welds in P. above.

SOUTHWEST RESEARCH INSTITUTE
WELDING PROCEDURE SPECIFICATION NO. W-4

-2-

This procedure specification covers Scope and Stainless Steel to Carbon Steel Pipe-to-Pipe Joint Weldments of the ASA Standard B16.9 Tee Test Specimen.

A. Base Metal

1. Carbon Steel Pipe - A106B
2. Stainless Steel Pipe - A312 TP 304L

B. Filler Metal

1. Consumable Insert - EB Type "A" or "J", 1/8", 308L
2. Bare Electrode - ASME-SA-371, Type 308L
3. Covered Electrode - ASME-SA-298, Type 309-16
4. Covered Electrode - ASME-SA-298, Type 308L-16

C. Process

The carbon steel pipe shall be overlaid using metal arc welding.

The closure pass shall be made by the Inert Gas-Tungsten Arc process, incorporating a consumable insert. A minimum of three subsequent passes shall be by the Inert Gas-Tungsten Arc process. Remaining passes shall be Metal Arc welding. All welding will be manual.

D. Gas for Inert Gas Welding

The shielding gas for the torch and backup shall be Argon, 99.995% pure.

E. Position

Pipe-to-pipe weldments shall be made in either the 1G or 2G position.

F. Preheat

No preheat will be used.

G. Interpass Temperature

Due to possible thermal damage to the strain gages interpass temperature shall not exceed 350°F.

H. Post-Heat Treatment

None

I. Weld Finish

Pipe-to-pipe weldments will be ground flush on the outside surface.

J. Joint Design

The initial joint design for the carbon steel pipe is shown in Table 1. After overlay is accomplished the joint design shall be as designated below.

The joint design at all joints will be a "V" groove with each bevel machined 37.5° to a diametral plane and contain a 1/32" maximum land. Pipe and tees will be counterbored to obtain a round section and tapered to the original dimensions at a 4:1 slope. Mismatch at any point will be less than ± 1/32 inch at the I.D. See Table 2. Ref: USAS B31.7 Fig. 1-727.3. 1(a).

K. Joint Preparation

1. Cleaning

All surfaces of the base metal, all filler wire, and the parts of any jigs or fixtures in contact with the joint or joint area shall be free of foreign materials. Immediately prior to fit-up and welding, an area 4 inches wide adjacent to the joint, and the joint edges shall be cleaned by brushing.

The base metal and backing bars shall be cleaned with Methyl Ethyl Ketone immediately prior to any tacking or welding operation. After cleaning, the joint area must not be touched by bare hands prior to welding.

2. Fit-up

The consumable insert shall be tacked into place in accordance with manufacturers recommended procedures. Tacks shall be cleaned by wire brushing. Additional tack welding utilizing the E. B. insert will be used to provide joint rigidity. All tacks must be back purged and cleaned (wire brushed) in accordance with the joint welding requirements.

IV-21

L. Assembly and Fixtures

No temporary welded supports shall be attached to the pipe or tee. Pieces may be assembled and tack welded in the 2G position then placed in the 1G position for welding. The necessary fixtures will be provided to assure proper alignment and prevent undue stresses during welding.

M. Joint Welding Procedure

1. Stainless Overlay

The carbon steel pipe shall be machined as shown in Table 1 and overlaid in the prescribed areas. Overlay shall be one pass of 309-16 rod and remaining passes with 308L-16 rod. A minimum of one pass shall be made with 308L-16. Rod size and amperage requirements are given in Table 1. The stainless weld deposit will then be machined to the requirements of Table 2.

2. Pipe-to-Pipe Weld

The closure pass and a minimum of three subsequent passes shall be performed using the Inert Gas-Tungsten Arc process. The backside of the joint shall be shielded with Argon gas. Pre-purge shall be sufficient to eliminate excessive oxidation of the root passes. The consumable insert shall provide the filler metal for the root pass.

Hand fed bare wire shall be used for subsequent passes incorporating the Inert Gas-Tungsten Arc process. When the TIG process is used, cracking in the crater will be prevented by filling the crater while down sloping the current with the auxiliary foot control in order to maintain the smallest possible weld pool. Particulars of rod size and amperage requirements are given in Table 2.

All remaining passes shall be made using 308L-16 covered electrode. Electrode size, number of passes and amperage requirements are given in Table 2.

All oxide (particles and film) from crater, weld beads, and base metal in the line of arc travel shall be removed before depositing each section of bead and from each completed weld bead.

Any cracks or blowholes that appear on the surface of any tack weld or bead of welding shall be removed by grinding.

All surface oxides must be removed by wire brushing or grinding before depositing the next successive bead of welding.

No peening or chipping of weld or base metal shall be allowed.

N. Welding Equipment

1. Inert Gas-Tungsten Arc Welding

Current Source

Linde AC/DC High Frequency Welder, 500 amp. The current will be DC, straight polarity.

Welding Torch

Linde Model HW-20 (water cooled)

Current Control

Foot Control

2. Metal Arc Welding

Current Source

Linde AC/DC High Frequency Welder, 500 amp. The current will be DC, reversed polarity.

O. Inspection

The Welding Inspector shall be the Research Assistant in charge of laboratory operation, the cognizant engineer or ORNL representative.

When the Welding Inspector believes inspection necessary, he will examine base metal or welds at any stage of fabrication; and when he has reason to question that this Procedure is being followed, the ability of the welder, or weld quality, he may require supplemental inspection, corrective action, or requalification of the welder.

P. Non-destructive Testing

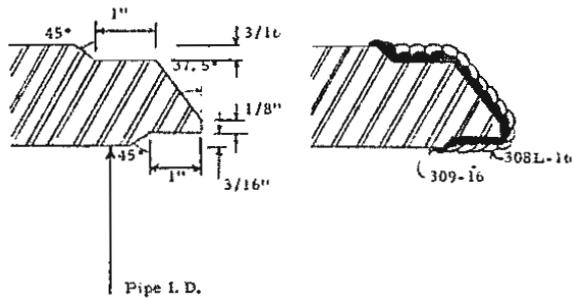

The finished weld will be radiographed in accordance with SwRI Specification R-1.*

Q. Qualification

The welding procedure specification shall be qualified in accordance with requirements of ASME Band PV Code, Section IX. Prior to removal of coupons for destructive examination, the test weld shall be nondestructively examined as required for production welds in P. above.

*These specifications shall meet the requirements of Paragraphs B-1 and B-3 (respectively) of Appendix B, B31.7.

APPENDIX V
RESULTS OF BRITTLE LACQUER TESTS

The brittle lacquer tests were performed to investigate the adequacy of the strain gage coverage. The tests were performed on models T-4, T-7 and T-8. The results of each test are detailed below.

V.1 Brittle Coating Analysis of T-4

The first stress coat cracks were noted in the crotch area at $\phi = 45^\circ$ when M3X = 13.6 foot-kips was applied to the branch. The sketchy crack pattern shown in Figure V.1 was photographed after a load of 41 foot-kips was applied. The same results were obtained when negative F3Z was applied with the first cracks appearing at $\phi = 315^\circ$ at a negative load of 4.8 kips. The pattern in Figure V.2 was photographed after a negative load of 12 kips had been applied.

When negative loads of M2Y and F2Z were applied, no significant crack patterns were obtained in the other two quadrants and the patterns in Figures V.1 and V.2 were essentially unchanged. However, some brittle coating cracks were obtained at the pipe-to-tee weld joints on the run.

The load M3X was applied a second time to a maximum load of 61.5 foot-kips and the crack pattern obtained is shown in Figure V.3.

The brittle coating test results indicated that no sharp stress gradients would occur in the crotch area when the model was subjected to out-of-plane bending and shear loads (assumed at this point to be the most severe loadings). The crotch area was adequately covered by a preplanned distribution of strain gage rosettes and no additional rosettes were needed.

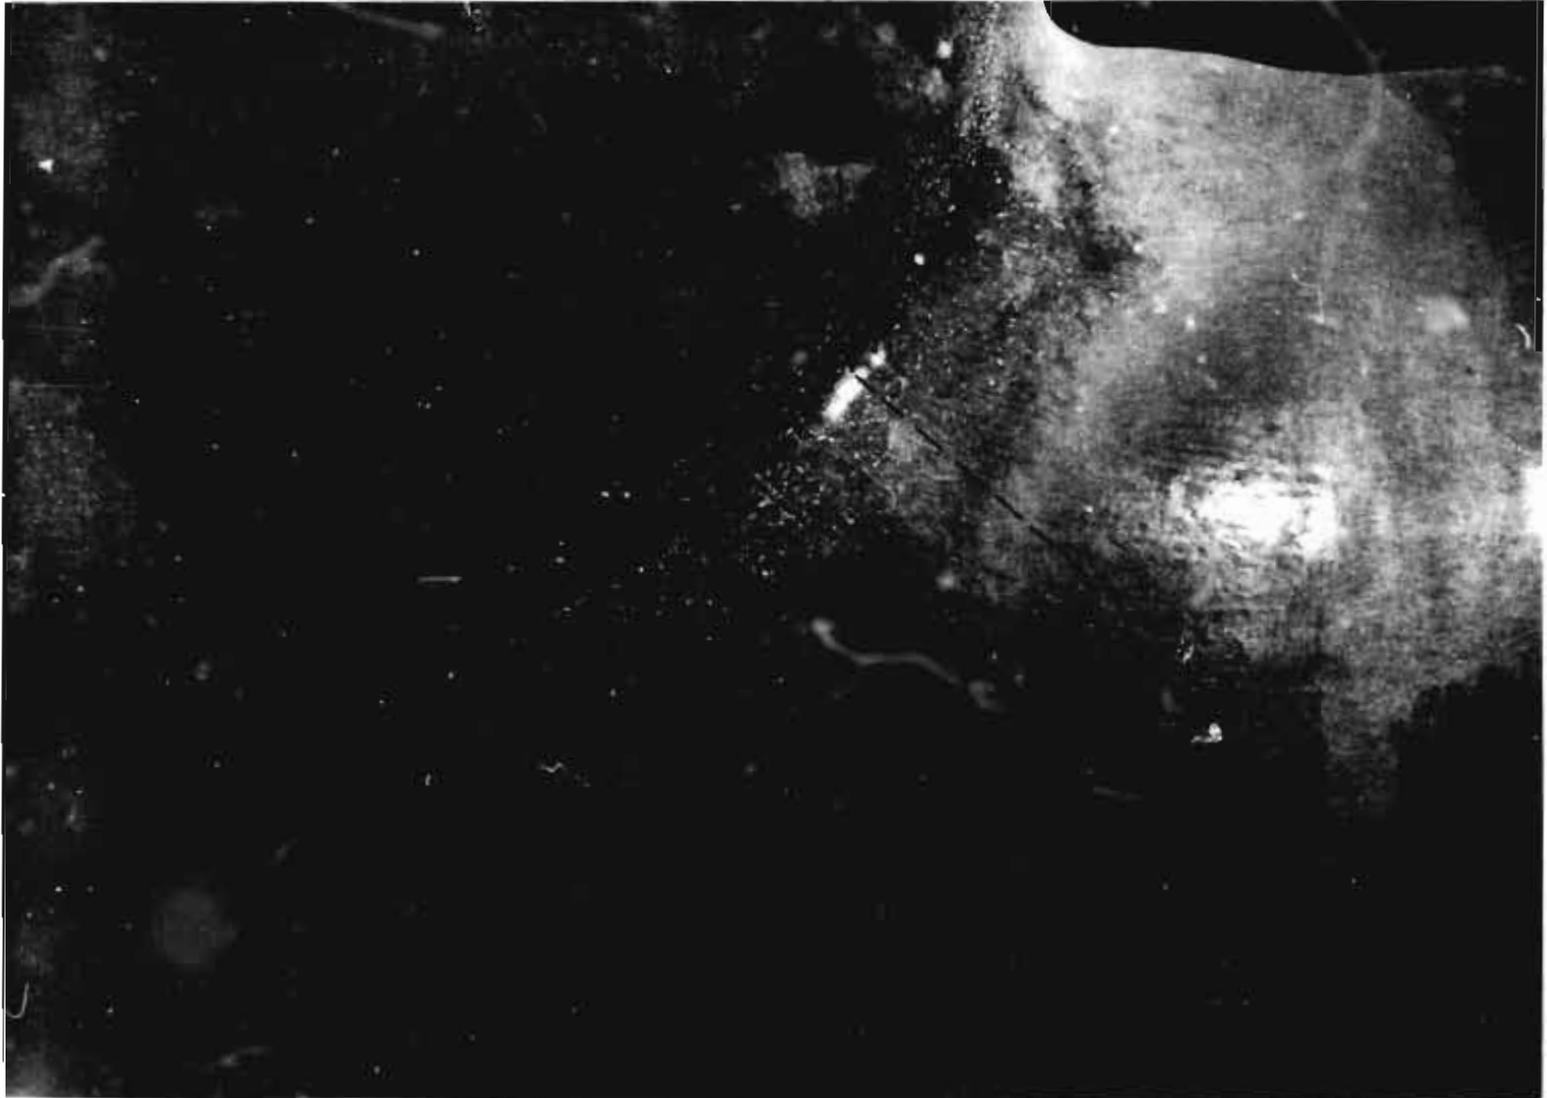

Figure V.1. Brittle Coating Pattern in the First Quadrant
at M3X = 41 Foot-Kips, Tee Number T-4

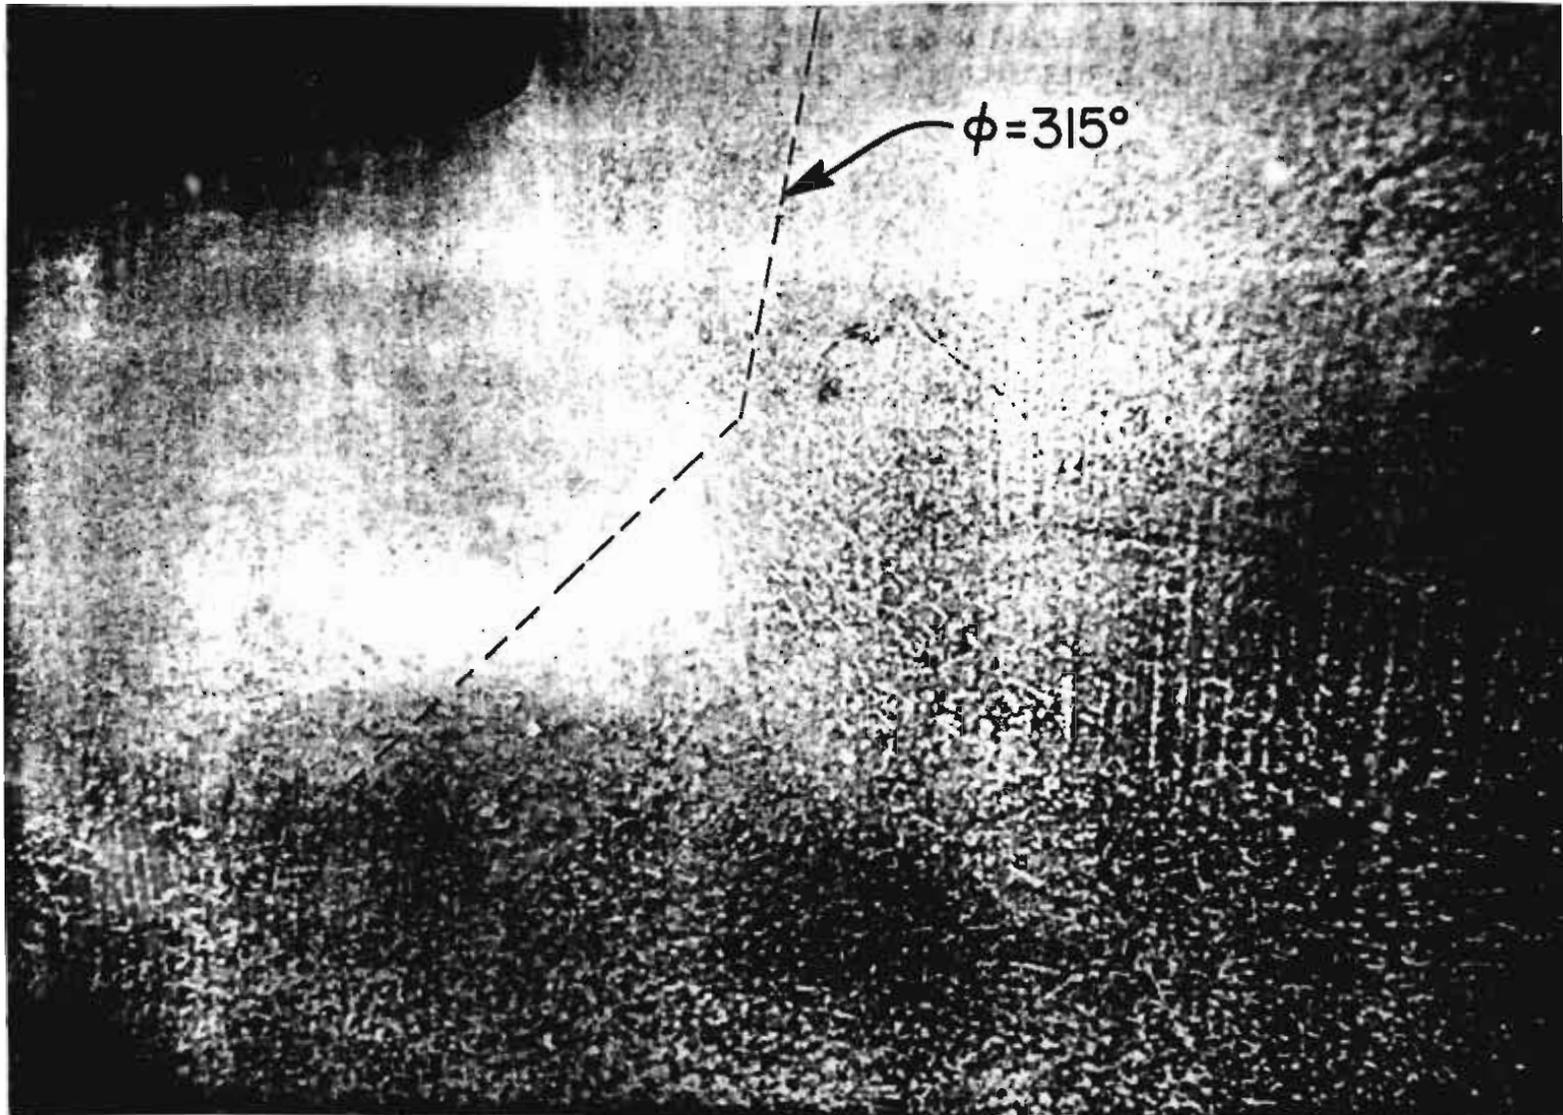

Figure V.2. Brittle Coating Pattern in the Fourth Quadrant
at F3Z = -12 Kips, Tee Number T-4

Figure V.3. Brittle Coating Pattern in the First Quadrant
at M3X = 61.5 Foot-Kips, Tee Number T-4

V.2 Brittle Coating Analysis of T-7

Brittle coating cracking occurred only after the last increment had been applied in each case. The M3X loading produced cracks in the area of the 67° ϕ line in the crotch. There were no sharp gradients indicated. The same results were obtained when the F3Z loading was applied except that the coating cracks were at a symmetrical location on the opposite side of the tee.

No other loads were applied as it was expected that M3X or F3Z would produce greater stresses than the other loads. This did not prove to be the case but it was, in the opinion of the experimenters, inconsequential. The rosette locations proved to give adequate coverage.

V.3 Brittle Coating Analysis of T-8

Slight brittle coating cracking occurred after the third increment had been applied in each case of bending moment. After the fourth increment fairly general cracking occurred as shown in Figure V.4. The M3X loading produced cracks in the area of the 270° ϕ line above the crotch and M3Z produced cracks at the 0° ϕ line above the crotch. There were no sharp gradients indicated. The same results were obtained when the F3Z loading was applied except that the coating cracks were at a symmetrical location on the opposite side of the tee. A maximum load of 2 kips was thought by a technician to be an increment. The brittle coating pattern at 4 kips is shown in Figure V.5.

No other loads were applied as it was expected that M3X, M3Z or F3Z would produce greater stresses than the other loadings. This proved to be the case and the brittle coating test indicated that the rosette locations were adequate for the load conditions applied.

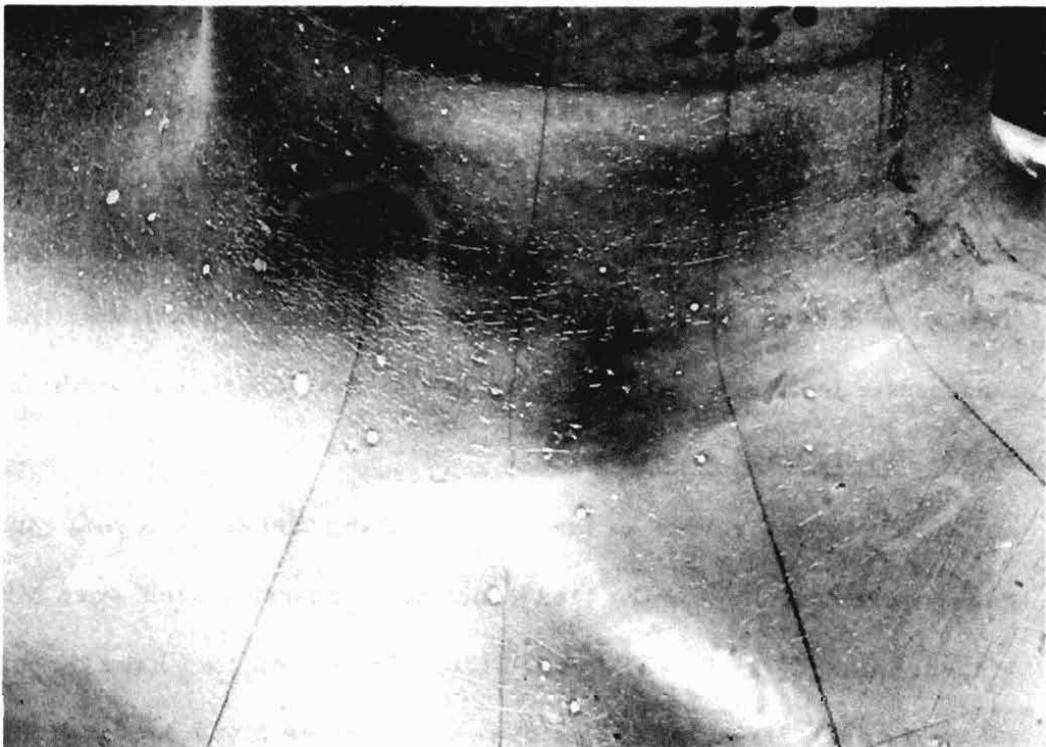

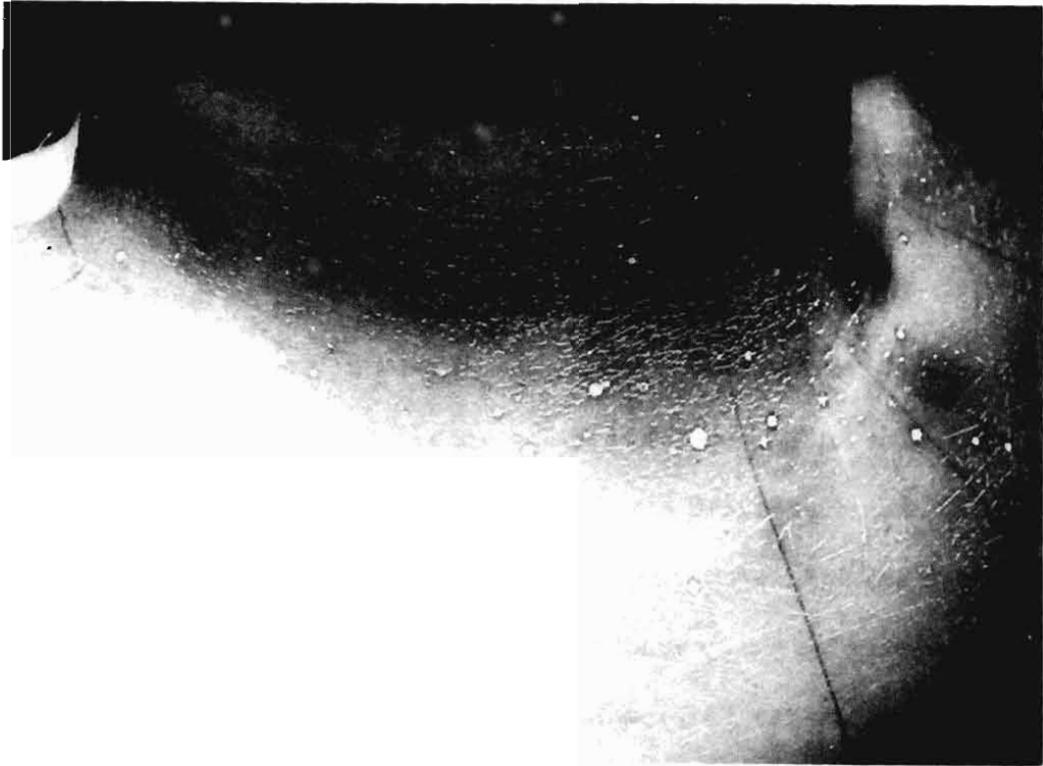

Figure V.4. Brittle Coating Cracks on T-8 After 14,000 Foot-Pounds Out-of-Plane and In-Plane Bending Applied to the Branch

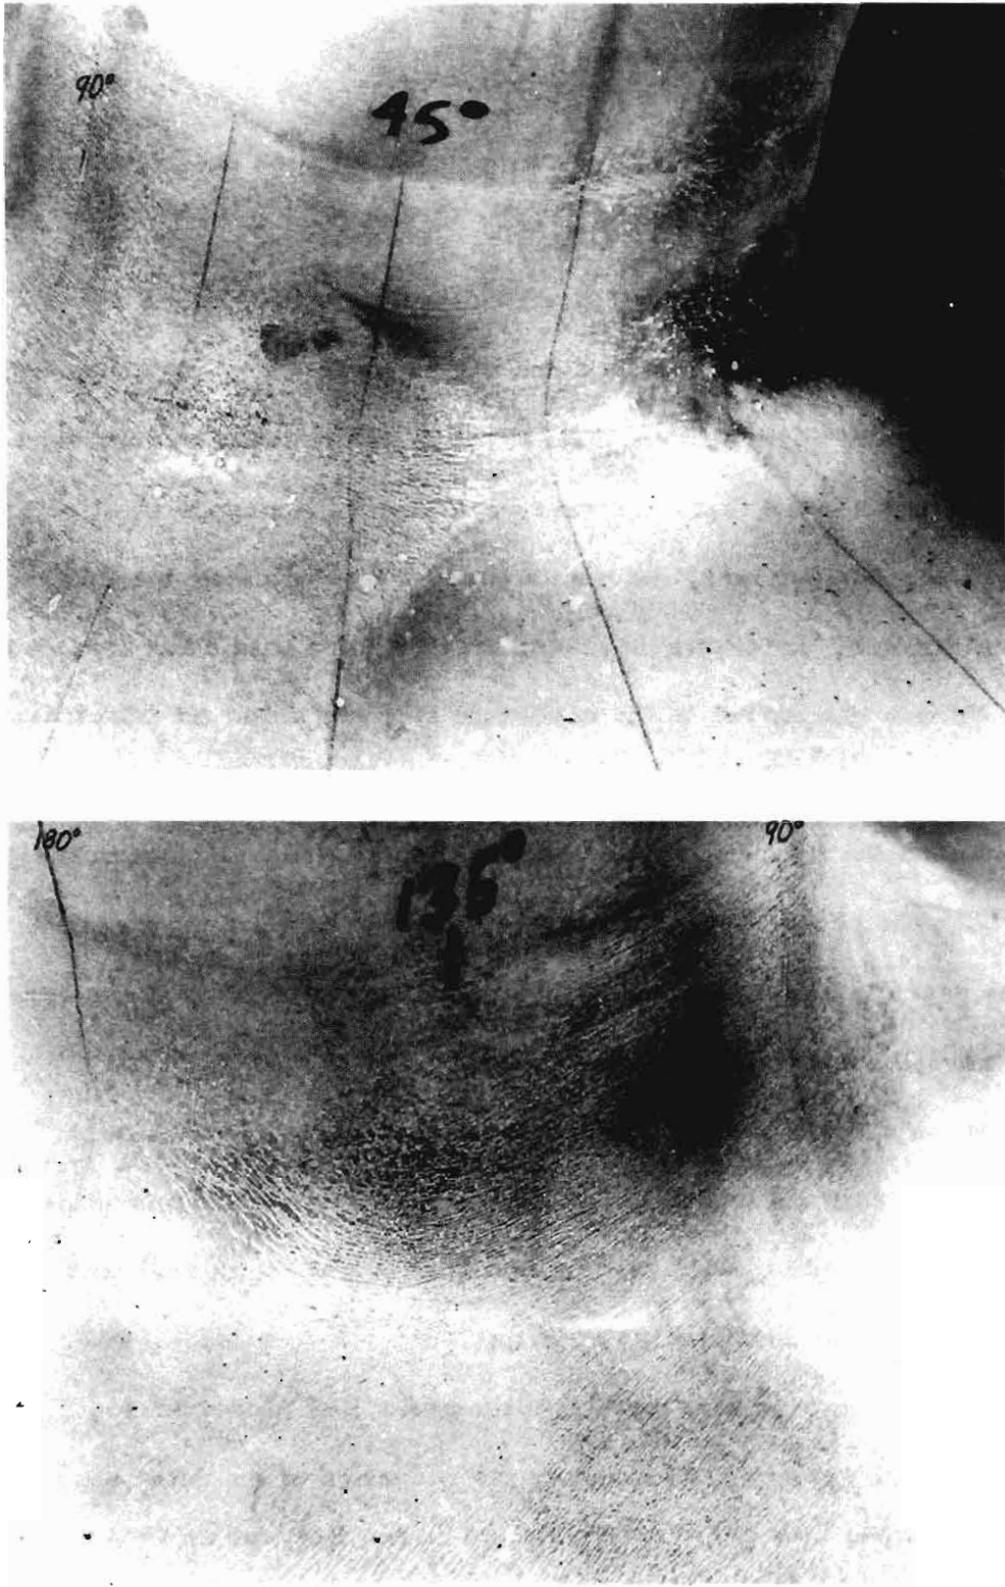

Figure V.5. Brittle Coating Cracks on 304L Stainless Steel Tee Number T-8 After 4 Kips Out-of-Plane Shear Applied to the Branch

APPENDIX VI

TABULATION OF STRAINS AND STRESSES AFTER BEING SUBJECTED TO
THE DIAGNOSTIC TESTS OF COMPUTER CODE NOSEY

The tabulations in this appendix are the output of computer program LINDA which uses the diagnostic procedures of subroutine NOSEY for identifying questionable data. The strains and stresses correspond to the load specified in each case. Except for the axial case, these loads have been chosen to give a nominal stress of 1000 psi in the pipe section to which the load was applied. For the axial load cases, the specified loads are the same as the transverse shear loads for the corresponding models. The nominal dimensions for the pressure case are those of the run pipe. Strain data from gages where more than 30% of the data were rejected are flagged with asterisks. A double asterisk indicates complete failure of the gage. The three columns showing principal stress information use "PHI" to specify the angle between the orientations of the number 2 gage of the rosette and the maximum principal stress. It should not be mistaken for the PHI used in this report to specify the orientation of the gage lines.

The data are arranged sequentially by model number. Specifically, T-4, T-6, T-7, T-8, and T-15. Under each model the loads are arranged in the following order; Pressure, M2X, -M2Y, -M2Z, F2X, -F2Y, F2Z, M3X, -M3Y, -M3Z, F3X, F3Y, F3Z.

T-4, INTERNAL PRESSURE LOADING

NOMINAL LOAD = 1.078E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, TORSIONAL MOMENT LOADING ON ROW, B2Y

NOMINAL LOAD = 6.188E 03 YOUNG'S MODULUS = 30.00E 06
 SUBFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '**' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, OUT-OF-PLANE MOMENT LOADING ON RUN, -H2Y

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, IN-PLANE ROTARY LOADING ON RUN, -H22

NOMINAL LOAD = 6.188E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, AXIAL FORCE LOADING ON RUN, P2X

NOMINAL LOAD = 1.003E 04 YOUNG'S MODULUS = 30.00E 05
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, IN-PLANE FORCE LOADING ON RUN, -P2Y

NOMINAL LOAD = 1.003E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, OUT-OF-PLANE FORCE LOADING ON BOX, P2Z

NOMINAL LOAD = 1.003E 03 YOUNG'S MODULUS = 30.00E 06
 SUBFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, OUT-OF-PLANE MOMENT LOADING ON BRANCH, H3X

NOMINAL LOAD = 6.188E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, TORSIONAL MOMENT LOADING ON BRANCH, -M3Y

NOMINAL LOAD = 6.188E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, IN-PLANE MOMENT LOADING ON BRANCH, -R3Z

NOMINAL LOAD = 6.188E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, IN-PLANE FORCE LOADING ON BRANCH, F3I

NOMINAL LOAD = 9.992E 02 YOUNG'S MODULUS = 30.00E 07
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, AXIAL FORCE LOADING ON BRANCH, P3Y

NOMINAL LOAD = 9.992E 03 YOUNG'S MODULUS = 30.00E 06
 SUBFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '+' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-4, OUT-OF-PLANE FORCE LOADING ON BRANCH, F3Z

NOMINAL LOAD = 9.992E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, INTERNAL PRESSURE LOADING

NOMINAL LOAD = 1.078E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.303

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, TORSIONAL MOMENT LOADING ON RUN, H2X

NOMINAL LOAD = 6.208E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6. OUT-OF-PLANE MOMENT LOADING ON RUM, -B2Y

NOMINAL LOAD = 6.208E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE STRESS = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, IN-PLANE MOMENT LOADING ON ROW, -B22

NOMINAL LOAD = 6.208E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, AXIAL FORCE LOADING ON RUN, F2Y

NOMINAL LOAD = 9.566E 03 YOUNG'S MODULUS = 30.00E 06
 SUPFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION OF MAXIMUM STRESS. (C.C. #)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE * INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, IN-PLANE FORCE LOADING ON RUN, -P2Y

NOMINAL LOAD = 9.566E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

I-6, OUT-OF-PLANE FORCE LOADING ON BOW, P22

NOMINAL LOAD = 9.566E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE STRESS = 0.0 POISSON'S RATIO = 0.300

PRI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6. OUT-OF-PLANE MOMENT LOADING ON BRANCH, H3X

NOMINAL LOAD = 6.208E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE * INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, TORSIONAL MOMENT LOADING ON BRANCH, -M3Y

NOMINAL LOAD = 6.208E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. †)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OF 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE *† INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, IN-PLANE MCHENT LOADING ON BRANCH, -M3Z

NOMINAL LOAD = 6.208E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6. IN-PLANE FORCE LOADING ON BRANCH, P3X

NOMINAL LOAD = 9.327E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, AXIAL FORCE LOADING ON BRANCH, PJY

NOMINAL LOAD = 9.327E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-6, OUT-OF-PLANE FORCE LOADING ON BRANCH, F3Z

NOMINAL LOAD = 9.3277 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE STRESS = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, INTERNAL PRESSURE LOADING

NOMINAL LOAD = 2.058E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES./INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE "*" INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, TORSIONAL MOMENT LOADING ON RUN, M2X

NOMINAL LOAD = 1.022E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '+' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, OUT-OF-PLANE MOMENT LOADING ON RUN, -82Y

NOMINAL LOAD = 1.022E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE *** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, IN-PLANE MOMENT LOADING ON RUN, -M2Z

NOMINAL LOAD = 1.022E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, AXIAL FORCE LOADING ON RUN, P2X

NOMINAL LOAD = 1.560E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, IN-PLANE FORCE LOADING ON RUN, -P2Y

NOMINAL LOAD = 1.564E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, OUT-OF-PLANE FORCE LOADING ON RUN, F23

NOMINAL LOAD = 1.564E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE "*" INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, OUT-OF-PLANE MOMENT LOADING ON BRANCH, B3X

NOMINAL LOAD = 1.022E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, TORSIONAL MOMENT LOADING ON BRANCH, -H3Y

NOMINAL LOAD = 1.022E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, IN-PLANE MOMENT LOADING ON BRANCH, -R3Z

NOMINAL LOAD = 1.022E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, IN-PLANE FORCE LOADING ON BRANCH, F3Y

NOMINAL LOAD = 1.576E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, AXIAL FORCE LOADING ON BRANCH, F3Y

NOMINAL LOAD = 1.576E 04 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-7, OUT-OF-PLANE FORCE LOADING ON BRANCH, P3Z

NOMINAL LOAD = 1.576E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. †)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE (†) INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, INTERNAL PRESSURE LOADING

NOMINAL LOAD = 6.369E 01 YOUNG'S MODULUS = 30.00E 06
 SUBFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, TORSIONAL MOMENT LOADING ON RUN, #21

NOMINAL LOAD = 3.925E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, OUT-OF-PLANE MOMENT LOADING ON RUN, -H2Y

NOMINAL LOAD = 3.925E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, IN-PLANE MOMENT LOADING ON RUN, -H22

NOMINAL LOAD = 3.925E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '**' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, AXIAL FORCE LOADING ON RUN, P2Y

NOMINAL LOAD = 6.048E 03 YOUNG'S MODULUS = 30.008 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, IN-PLANE FORCE LOADING ON RUN, -F2Y

NOMINAL LOAD = 6.0482 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8. OUT-OF-PLANE FORCE LOADING ON RUN, P22

NOMINAL LOAD = 6.048E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, OUT-OF-PLANE MOMENT LOADING CN BRANCH, M3Y

NOMINAL LOAD = 7.083E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, TORSIONAL MOMENT LOADING ON BRANCH, -H3Y

NOMINAL LOAD = 7.083E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROCINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, IN-PLANE MOMENT LOADING ON BRANCH, -H32

NOMINAL LOAD = 7.083E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, IN-PLANE FORCE LOADING ON BRANCH, P3X

NOMINAL LOAD = 1.116E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROCINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8. AXIAL FORCE LOADING ON BRANCH, P3Y

NOMINAL LOAD = 1.116E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE *** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-8, OUT-OF-PLANE FORCE LOADING ON BRANCH, P3Z

NOMINAL LOAD = 1.116E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, INTERNAL PRESSURE LOADING

NOMINAL LOAD = 6.369E 01 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE (*) INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, TORSIONAL MOMENT LOADING ON RUN, H2Y

NOMINAL LOAD = 3.925E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. +)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, OUT-OF-PLANE MOMENT LOADING ON RUN, -R2Y

NOMINAL LOAD = 3.925E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, IN-PLANE MOMENT LOADING ON RUN, -M²Z

NOMINAL LOAD = 3.925R 03 YOUNG'S MODULUS = 30.00R 06

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, AXIAL FORCE LOADING ON RUN, P2X

NOMINAL LOAD = 6.038E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. °)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, IN-PLANE FORCE LOADING ON RUN, -P2Y

NOMINAL LOAD = 6.038E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C. C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE (*) INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, OUT-OF-PLANE FORCE LOADING ON RIB, P22

NOMINAL LOAD = 6.038E 02 YOUNG'S MODULUS = 30.03E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION OF MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OF 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE * INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, OUT-OF-PLANE MOMENT LOADING ON BRANCH, H3Y

NOMINAL LOAD = 7.083E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, TORSIONAL MOMENT LOADING ON BRANCH, -H3Y

NOMINAL LOAD = 7.083E 02 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, IN-PLANE MOMENT LOADING ON BRANCH, -M3Z

NOMINAL LOAD = 7.083E 02 YOUNG'S MODULUS = 30.03E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE ** INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, IN-PLANE FORCE LOADING ON BRANCH, P3Y

NOMINAL LOAD = 1.11E 02 YOUNG'S MODULUS = 30.03E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, AXIAL FORCE LOADING ON BRANCH, F3Y

NOMINAL LOAD = 1.111E 03 YOUNG'S MODULUS = 30.00E 06
 SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)
 THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.
 THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

T-15, OUT-OF-FLAME FORCE LOADING ON BRANCH, P3Z

MONIHAL LOAD = 1.11E 02 YOUNG'S MODULUS = 30.00E 06
SURFACE PRESSURE = 0.0 POISSON'S RATIO = 0.300

PHI IS THE ANGLE MEASURED FROM THE REFERENCE DIRECTION TO THE DIRECTION FOR MAXIMUM STRESS. (C.C. *)

THE TOLERANCE USED FOR DATA ELIMINATION IS THE MAXIMUM OF 8.0 MICROINCHES/INCH OR 15.0 PERCENT OF THE MAXIMUM STRAIN FOR THAT GAGE.

THE '*' INDICATES THAT MORE THAN 30 PERCENT OF THE DATA FOR THAT GAGE WAS ELIMINATED.

APPENDIX VII

TABULATION OF STRESS INTENSITIES

Table VII.1 presents the adjustments made in values of the stress intensities calculated by LINDA. These adjustments are made according to the procedure of Section 3.1.2. Table VII.2 is a complete presentation of normalized stress intensities.

In Table VII.2 the loads are organized in the following order: Pressure, F2X, -F2Y, -F2Z, M2X, -M2Y, -M2Z, F3X, F3Y, F3Z, M3X, -M3Y, -M3Z. Under each load case the models are presented sequentially, that is T-4, T-6, T-7, T-8, T-15.

Key to Table VII.2

-  = Local Maximum
 = Adjusted Data Point

APPENDIX VIII
COMPUTER PLOTS OF STRESS INTENSITIES

Three types of stress intensity plots are presented in this appendix: projected length along maximum intensity phi line vs. stress intensity, circumferential location vs. maximum stress intensity and stress intensity contour plots. Adjusted data points have been circled in the first two sets of plots. For those load cases where the maximum stress intensity occurred at an intermediate gage location on the crotch line (i.e., 11° , 33° , 56° , 78° , 194° , 213° , 236° and 258°) no gage line plots were generated. These intermediate values were not used in generating the circumferential plots.

The projected gage line length used for the abscissas of the first set of plots is computed by first projecting the maximum stress intensity gage line onto the diametral plane. The resulting curve is then rotated 45° and projected onto a straight line. The resulting lengths are designated x'' . Gages on the branch have negative values of x'' and run gages have positive values of x'' . The derivation of x'' is illustrated in Figure VIII.1.

Each set of plots has been organized according to load type and model number in the following manner. The loads are presented in this order, Pressure, F2X, -F2Y, -F2Z, M2X, -M2Y, -M2Z, F3X, F3Y, F3Z, M3X, -M3Y and -M3Z. Under each load type the models are ordered sequentially, that is, T-4, T-6, T-7, T-8 and T-15. Under each model the 0° - 90° quadrant is presented first and then the 180° to 270° quadrant.

APPENDIX IX
DEFLECTION DATA FROM DIAL INDICATORS

This appendix presents tabulations of deflection data obtained from the sixteen dial indicators located on each model. Dial locations are shown in Figure IX.1. The data is arranged in the following sequence under each tee: Pressure, M2X, -M2Y, -M2Z, F2X, -F2Y, F2Z, M3X, -M3Y, -M3Z, F3X, F3Y, F3Z.
