

LASERS IN ART CONSERVATION

Dr. John C. Miller*, Oak Ridge National Laboratory

ABSTRACT

Daguerreotypes were the first form of photographs and were popular between 1840 and 1860, after which they were superseded by more modern techniques. The daguerreotype image is composed of silver microcrystals of varying size and density on a silver-coated copper substrate. Nineteenth century daguerreotypes, over the intervening 140 years, have suffered degradation and oxidation, which has greatly reduced their historic and artistic value. Laser ablation techniques have been previously explored for use in the characterization, dating, and restoration of historic paintings, parchments, stained glasses, and statues.

This seminar will describe the use of a number of modern surface science techniques (especially those using lasers, mass spectrometry, and microscopy) to characterize and analyze both normal and degraded daguerreotypes. Then, attempts to use laser ablation techniques for cleaning and restoring damaged nineteenth century samples will be described. The optimal wavelength, pulse length, pulse energy, and focussing conditions are critical for effective cleaning while preventing damage to the fragile image

In related studies, a technique is described to produce digital maps of the tarnish layer by observing the difference between “positive” and “negative” photographs of a damaged daguerreotype. Mathematical models of the tarnish growth process and of laser cleaning allows the simulation of the appearance of daguerreotypes as a function of their age and the extent of treatment.
